On thinking over the symptoms the patient discovered that they stood to her for the chief symptoms of pregnancy, especially the feeling of distension, which often compelled her to loosen her clothes. She then revealed that she was often greatly worried by the fear that she was pregnant, although she realised that it was irrational and fantastic. The connexion between certain articles of diet and pregnancy had been formulated, unconsciously, in the following way. She knew, as quite a small child, that babies grew inside their mothers and she supposed that they grew out of the food that was eaten,[1] but observing that they did not occur promiscuously, she argued that some special sort of food must be necessary to start the process of growth. A warning not to eat watercress, since it might contain frog's eggs which would "grow inside her," seemed to provide a clue, and she thought that any food that contained life might cause pregnancy, hence her fear in later years of uncooked food, and especially of watercress and salads. Learning from the Old Testament that the Jews were forbidden to eat meat with the blood in it because "blood is the life," she assumed that the prohibition was imposed to prevent people in general from becoming pregnant, a theory that determined her reaction to underdone meat, tomato soup, and to all food that in any way resembled blood. The story of Rachel and the mandrake root accounted for the power of all root vegetables to bring on the imagined symptoms of pregnancy, and the phrase "God breathed the breath of life into Adam" for her reaction when she was breathed upon by a man.

It will be noted that the patient's mode of thought was quite logical and led, in accordance with the limited data at her disposal, inevitably to the fantastic conclusions that were expressed in the neurosis. Two pieces of folk-lore (the mandrake root and the "breath of life") were accepted with the characteristic readiness of a child and built up into her fantasies, while a close parallel to the rest of her behaviour towards food may be found in many primitive practices and superstitions. Among the Esquimaux of Baffin's Land the young girls are forbidden to eat eggs lest they conceive, and among the Coast-Salish Indians of N.W. America certain meats are proscribed for the same reason.[2] Blood itself is very commonly used in folk medicine as a remedy for barrenness. But examples of the use of magic food as an agency in conception may be found in modern times and nearer home, and Hartland records the case of a young married woman who stole some sausages in 1876 from a shop in Theobald's-road and ate them raw on the spot in order to have a child, with the result, as she related, that nine months later to a day a boy was born who was "fat and rolly like a sausage." It is interesting to notice that this story curiously resembles a dream, much as the tabus of the Esquimaux and the North American Indians resembles a neurosis.

Although the conclusions reached by the patient in childhood, and repeated later in her neurosis, are also found among primitive people, it does not seem necessary to invoke any stirrings of ancestral memory to explain the coincidence, seeing that both the child and the primitive are alike in their relative ignorance of the physiological processes, and may, therefore, be expected to arrive at similar results if they argue from similar data.

The general idea that food contains life, and that the vital energy of the plant or animal from which it was derived is not quite extinct, but can be directly imparted to the individual who eats it, was developed intensively by the patient and employed in the construction of her symptoms. But the idea seems to exist, in a hazy way, as a popular belief, if we may judge from the obstinate faith in the food value of dietetic beef-tea, &c., and the recurrent popularity of régimes dictating unfired food or raw meat. As a quasi-magical attitude towards food the general idea has obvious drawbacks, but the advantage

Obituary.

SIR ANDREW JOHN HORNE, F.R.C.P. IREL.

Sir Andrew Horne, joint Master of the National Lying-in Hospital, Dublin, died on Sept. 5th at his residence, Merrion-square, Dublin, at the age of 68, after a long illness. He had been for many years one of the leading obstetric and gynæcological physicians in Ireland. Born in Ballinasloe, Co. Galway, Horne spent his schooldays at Clongowes Wood College, Co. Kildare, proceeding to Dublin and Vienna for his medical training. He became a Licentiate of the Royal College of Surgeons in Ireland in 1877, and a Fellow of the Royal College of Physicians of Ireland in 1885. Of the latter College he was Vice-President from 1894 to 1896, and President from 1908 to 1910. He early devoted himself to the special study of obstetrics, and was assistant Master of the Rotunda Hospital from 1880 to 1883. On the foundation of the National Lying-in Hospital in 1894 Horne was chosen as Master, a position he continued to hold up to his death, though in recent years a joint Master shared the duties. At the close of his period of presidency of the Royal College of Physicians he was knighted by Lord Aberdeen, then Lord-Lieutenant of Ireland.

During his long career in the profession Horne was a steady and conscientious worker, and for many years he enjoyed a large practice. He took much interest in the work of the Section of Obstetrics of the Royal Academy of Medicine in Ireland, of which section he was President more than once. Though he did not often write for the journals, he was a frequent contributor to the Proceedings of the Academy, and attended its meetings with great regularity. In professional affairs generally he took an active part, and was a member of many committees, among others the Central Midwives Board. Personally he was a man of great charm, genial, sympathetic, and unassuming. Both in the profession and outside it he had innumerable friends. Of his surviving family one son is a member of the medical profession.

ALBERT HAWORTH, M.Sc., M.B., CH.B. MANCH.

IT is with sincere regret that we record the death of Dr. Albert Haworth, assistant lecturer in chemical pathology to the Manchester Royal Infirmary, at the age of 36. Last July, in the course of his duties, Dr. Haworth carried out a post-mortem examination in the Royal Infirmary, in doing which he received a cut on his finger from a projecting rib of the cadaver. An infection followed which subsequently seemed to disappear, but later grave symptoms manifested themselves and he was removed to the infirmary, where he died on Sept. 6th from pneumonia. Mr. C. W. W. Surridge, the Manchester City coroner, in returning a verdict of accidental death, said Dr. Haworth had died from an injury received whilst carrying out important public duties, and his death in these circumstances was very regrettable. Dr. Haworth was born at Harwood, near Blackburn. In 1912 he took the degree of M.Sc. at Manchester University, specialising in chemistry. Attracted to medicine, he graduated as M.B., Ch.B. in 1920, but his bent was rather towards the scientific side of medicine than its practical aspects, and more especially did chemical pathology appeal to him. He was for a time a demonstrator in the pathological department and later studied pathological chemistry at St. Thomas's Hospital, London. Quite recently he was appointed lecturer in chemical pathology at the University of Leeds and should have taken up his duties there next month. Dr. Haworth was married, and to his widow, who is also a member of the medical profession, we extend our heartfelt sympathy.

THOMAS SYDNEY SHORT, M.D. LOND., D.P.H. CAMB.

Dr. T. Sydney Short, of 85, Edmund-street, Birmingham, senior physician to the General Hospital, Birmingham, died recently at Claverdon, Warwick, while on holiday. Dr. Short was born in 1860 at Sheffield. He received his medical education at University College, London, and qualified as M.R.C.S. Eng. and L.S.A. in 1883. Two years later he took the degree of M.B., and in 1886 he gained the medal in hygiene at University College, obtaining the D.P.H. Cambridge in the same year.

In 1891 he became an M.D. Lond. and M.R.C.P. Lond. On first qualifying, Dr. Short held the post of house physician at King's College Hospital, and later that of assistant demonstrator in anatomy at the medical school. After a period as resident medical and surgical officer at Jaffray Suburban Hospital, Birmingham, he was appointed assistant honorary physician to the Birmingham General Hospital in 1891, and remained on the staff of that institution until his death. He was also consultant physician to the General Dispensary, Birmingham. Dr. Short contributed several articles to medical journals, dealing with such subjects as the treatment of epilepsy, the treatment of arthritis, and the dietetic treatment of gout and kindred conditions.

Medical News.

UNIVERSITY OF OXFORD.—Lieut.-Colonel Sir Charles H. Bedford, who recently received the honorary degree of Doctor of Civil Law (D.C.L.), was attached for 22 years to the Indian Medical Service. His work in India was carried out mainly as chemist to the Government, and he conducted a long series of successful scientific and technical researches on alcohol for the Customs and Excise Departments. On retiring from the Service in 1911 he received the honour of knighthood. Since then his expert knowledge on power and industrial alcohol development has been placed at the disposal of the Colonial Office, and he was the first general manager of the Association of British Chemical Manufacturers. Edinburgh and St. Andrews Universities have previously conferred upon him honorary degrees.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—The Fellowship of Medicine and Post-Graduate Medical Association announce that an intensive course in general medicine and surgery and the various special departments will be given at the Westminster Hospital, S.W. 1, from Sept. 22nd to Oct. 3rd, from 10.30 A.M. to 5.30 P.M. each day. The first lecture will be given by Mr. Walter Spencer at 10.30 A.M. on Monday, Sept. 22nd, on Oral Sepsis. The names of those wishing to attend should be sent to the Secretary of the Fellowship of Medicine, 1, Wimpole-street, W. 1, if possible by Sept. 19th.

THE Central Association for Mental Welfare has arranged a course in mental diseases for secretaries of associations for mental welfare and for other experienced social workers, to be held from Monday, Oct. 27th, to Saturday, Nov. 1st, at the Maudsley Hospital, Denmark Hill, London, S.E., under the direction of Dr. Edward Mapother, medical superintendent of the hospital. The course will consist of lectures on mental diseases and mental deficiency, with clinical demonstrations at the Maudsley and County Mental Hospitals, and at certified institutions for defectives. Early application must be made to the Hon. Secretary, 24, Buckingham Palace-road, London, S.W. 1.

THE LATE DR. V. F. ALLEN.—Vernon Francis Allen, of Swaffham, Norfolk, whose death at the age of 58 occurred recently as the sequel to a motor accident in which he was injured some months ago, was surgeon to the Swaffham Cottage Hospital and a well-known local figure. He was the third son of Christopher Allen, J.P., of Stone Hall, Glandore, Co. Cork, and qualified L.R.C.S. & P. Edin. and L.R.F.P.S. Glasg. in 1891. A year or two later Dr. Allen began to practise in Swaffham, first as assistant, later as partner to Dr. R. B. Marriott, eventually in 1898 taking over the entire work. In 1898 he also became an urban district councillor, a position he held until 1910. In 1922 he was joined in his practice by Dr. W. B. Cathcart. Dr. Allen took a keen interest in breeding greyhounds and in coursing. He is survived by a widow and two children.

at once that the determining factor leading to bad results is to be sought in the patient, and the evidence at hand bears this out. Gastro-enteritis, especially of a hæmorrhagic type, is apparently a contra-indication for the use of carbon tetrachloride, as are cirrhosis of the liver, nephritis, or acute or chronic alcoholism. In other words, any conditions favouring absorption of the drug are contra-indications, as are existing lesions in such viscera as may be habitually injured to some slight extent by the small amount of the drug usually absorbed. A seriously damaged liver or kidney may not tolerate a slight additional injury.

As regards santonin for removing hook-worms, there are a number of reports of its use in human and veterinary medicine, showing that it is entirely ineffective. I have given to dogs large amounts of santonin in single dose and in doses repeated for long periods, and found it entirely ineffective against hook-worms.

With reference to whether carbon tetrachloride is a true anthelmintic, I am of the opinion, after ten years spent in the experimental investigation of anthelmintics, that it is. The word anthelmintic is a generic term, just as the word poison is a generic term, the anthelmintics being a heterogeneous group of poisons which poison parasitic worms. How they poison them is of little importance from the standpoint of medical practice and results, although it is a matter of great importance from a scientific standpoint. If we make academic distinctions in any field we cloud the field and waste time. The distinction between vermifuge and vermicide is another academic distinction of no real value whatever. One may say that a vermifuge drives out worms, alive or dead, and that a vermicide kills worms and may or may not have sufficient purgative action to remove them promptly. But if the worms are removed it is of no importance whatever whether they are alive or dead; a worm removed is for all practical purposes a worm dead, and whether the drug kills it or it dies as a result of removal from the only environment in which it can live is of no consequence. Whether an anthelmintic is also purgative or is not purgative is of interest only as the administration of a separate purgative is unnecessary or is necessary. The subject of anthelmintic investigation would proceed faster if we would drop these antiquated terms, adopted at a time when we knew almost nothing of anthelmintic action, and speak and write in terms of anthelmintic action as one thing, and of purgation as another. Anthelmintics may be actually purgative, as in the case of arecoline hydrobromide; mildly laxative, as is the rule in the case of carbon tetrachloride; or actually constipating, as in the case of chenopodium. Since purgation is desirable in the case of all anthelmintics, it follows that such drugs as arecoline hydrobromide should not be accompanied by a purgative, since purgation is assured in advance, that such drugs as carbon tetrachloride should be accompanied by a purgative to ensure purgations, and that such drugs as chenopodium should be accompanied by a purgative, additional purgatives or enemas being given a few hours later if prompt purgation does not follow the initial dose.

So far as any knowledge as to the specific action of anthelmintics on worms is concerned we know practically nothing, and this is a subject which merits extensive investigation. From a practical standpoint we are directing attention at present to finding anthelmintics which will be effective and safe. An ideal anthelmintic would be 100 per cent. effective and 100 per cent. safe. That we shall ever find such a poison, one injuriously affecting one kind of animal, the parasite, and in no wise injuriously affecting another kind of animal, the host, is unlikely. Whether a knowledge of the manner in which anthelmintics affect parasites would aid in any way in finding an approximately ideal anthelmintic is doubtful, but we should have the information for what it might be worth as well as for its purely scientific interest. At the present time the most promising line of attack in solving the problems of anthelmintic medication lies along the lines of correlation of anthelmintic efficacy with the chemical composition and physical properties of anthelmintics, and investigations along these lines are already beginning to point to some conclusions which promise to be of considerable value.

I am, Sir, yours faithfully,

MAURICE C. HALL,
Zoologist.

United States Bureau of Animal Industry,
August 26th, 1924.

UNIVERSAL ANÆSTHETIC APPARATUS.

To the Editor of THE LANCET.

SIR,—Dr. R. J. Clausen criticises the combined anæsthetic pump and suction apparatus on the ground that it is fitted with rubber tubing for its connexions. I agree that theoretically it would be better to have metal pipes fixed with nuts and unions, making the whole apparatus into one rigid unit, but practically there are many objections. In the first place, the detachability of the bottles and other parts for cleaning would be impaired. Secondly, a large number of soldered joints tend towards fracture when in hard use; many car manufacturers are now, in fact, substituting flexible pipes for rigid ones where practicable. Furthermore, if the whole system were absolutely gas-tight at any pressure an accident might arise if the blow-off device became inoperative. Lastly, expense is a serious matter—at any rate to the anæsthetist. The pressure-tubing used in the apparatus is made of composition which does not perish in several years of use and the joints are gas-tight up to 70 mm. Hg. The only serious objection to its use is that, if a dry gas is forced through it at very high pressure, it is possible for it to become electrically charged, and a small static spark may result. It is conceivable that a highly explosive mixture such as ethylene-oxygen might become ignited in this way, but I should imagine that the risk is too infinitesimal to be worth considering.

I am, Sir, yours faithfully,

C. LANGTON HEWER.

York-terrace, Regent's Park, N.W., Sept. 6th, 1924.

THE CLINICAL THERMOMETER AS A CARRIER OF INFECTION.

To the Editor of THE LANCET.

SIR,—There is no doubt about the risk, but as the thermometer is a necessary equipment for the diagnosis of disease why not minimise this risk by the use of a "family" thermometer? In a great number of patients' houses now we find clinical thermometers provided. The class of people who use them do not like the idea of having the doctor's thermometer put in their mouths after being used by strangers in all forms of disease. If every household had its own clinical thermometer it would prevent the spread of infection to others.

I am, Sir, yours faithfully,

Berkeley-street, W., Sept. 9th, 1924. HENRY DUTCH.

DONATIONS AND BEQUESTS.—The executors of the late Sir Samuel Turner, of Rochdale, one of the pioneers of the asbestos industry, announce that he has left, in addition to the endowment of other charities, £3000 to Rochdale Infirmary, £1000 each to the Rochdale District Nursing Association and the Crippled Children's Union, £500 to the Rochdale and District Society for the Blind, and £1000 to the National Children's Home and Orphanage.—Mr. Walter John Tillett, Penarth, shipowner, left £10,000 to the King Edward VII. Hospital, Cardiff (Cardiff Infirmary), upon trust to devote the income firstly towards the maintenance of the Elizabeth Tillett bed in memory of his wife, and subject thereto for the general purposes and upkeep of the hospital.—Miss Eliza Moore, of St. Annes-on-the-Sea, Lancs, among other bequests, bequeathed £1000 to the Beckett Hospital and Dispensary, Barnsley, Yorks, to endow four beds to be known as the William Moore, Elizabeth Moore, Eliza Moore, and May Elizabeth Moore beds; £1000 to Dr. Barnardo's Homes, £2000 to Dr. Stephenson's Wesleyan Orphan Homes, £2000 to the National Society for the Prevention of Cruelty to Children, £2000 to the National Institution for the Deaf and Blind, and £2000 to the National Institution for the Dumb. Altogether Miss Moore left over £25,000 to various charities.—Mr. Albert Henry Bruton left £500 to the Gloucester Royal Infirmary.

Nottingham General Dispensary.—Res. S. £250.
Pietermaritzburg, S. Africa, Grey's Hospital.—H.S. £400.
Plymouth, South Devon and East Cornwall Hospital.—H.S. and H.P. £100 and £50 respectively.
Prince of Wales's General Hospital, Tottenham, N.—H.S.'s, H.P., Each £150. Also Jun. H.S. and H.P. Each £110.
Queen's Hospital for Children, Hackney-road, E.—H.S. £100.
Royal Ear Hospital, Dean-street, Soho.—Reg. £50.
Royal Free Hospital, Gray's Inn-road, W.C.—Med. Reg.
Royal National Orthopædic Hospital, 234, Great Portland-street, W.—Two H.S.'s. Each £150.
Royal Naval Medical Service.—Surg. Lieuts. 25s. per day.
St. Marylebone General Dispensary, 30, Marylebone-lane, W.—Hon. P.
St. Marylebone Hospital, Ladbroke-grove, W.—Third Asst. M.O. £300.
St. Peter's Hospital for Stone, Henrietta-street, Covent Garden, W.C.—H.S. £75.
Seamen's Hospital Society, Greenwich.—H.S. for Albert Dock Hospital. Also H.P. and H.S. at Dreadnought Hospital. Each £150.
Shanghai Municipal Council, Public Health Department.—Asst. Path. £1250.
Sheffield Royal Infirmary.—Res. Surg. O. £200.
South London Hospital for Women, Clapham Common, S.W.—H.P. and three H.S.'s. Each £50.
West London Hospital, Hammersmith-road, W.—H.P. and two H.S.'s. Each £100.
Winchester, Royal Hampshire County Hospital.—H.P. £150.

The Chief Inspector of Factories, Home Office, London, S.W. announces a vacant appointment at Kirkwall, Orkney.

Births, Marriages, and Deaths.

BIRTHS.

Barry.—On August 31st, at The Chestnuts, Roos, E. Yorks. the wife of J. H. Barry, L.R.C.P. & S. Irel., of a son.

Bastian.—On Sept. 5th, at St. David's-road, Southsea, the wife of Surgeon-Commander W. Bastian, R.N., H.M.S. *Dryad*, of a daughter.

Hadfield.—On August 31st, at "The Red House," Beaconsfield, the wife of J. A. Hadfield, M.B., Ch.B. Edin., of a son.

Marks.—On Sept. 3rd, at Inverness-terrace, Hyde Park, the wife of Maurice J. Marks, L.D.S. R.F.P.S. Glasg., of a son.

McElligott.—On Sept. 6th, at 177, Westmount-road, Eltham, S.E.9, to Dr. Geraldine, wife of Dr. E. T. McElligott—a son.

Reichwald.—On Sept. 1st, at Timber Hill, Ashtead, Surrey, the wife of Dr. M. B. Reichwald, M.B., B.S. Lond., of a daughter.

Stocker.—On Sept. 2nd, at Glebe Croft, Bakewell, the wife of Major C. J. Stocker, M.D. Camb., I.M.S., of a son.

MARRIAGES.

Wilson—Curjel.—At Christ Church, Simla, on the 16th August, 1924, by the Revd. C. H. Hemming, William Robert Wilson, Indian Civil Service, to Dagmar F. Curjel, M.D. Glasg., D.P.H. Camb., Assistant to the Inspector-General of Civil Hospitals, Punjab.

Wood—Wolseley.—On Sept. 6th, at St. Stephen's, Twickenham, Edward Archer Wood, L.R.C.P. Lond., M.R.C.S. Eng., L.S.A., Dulwich, to Minnie Bathurst Wolseley, daughter of Henry John Wolseley, M.B., C.M. Edin., and Mrs. Wolseley, also of Dulwich.

DEATHS.

Allen.—On August 30th, at Swaffham, Norfolk, Vernon Francis Allen, L.R.C.P. & S. Edin., aged 58.

Armstrong.—On August 31st, at Victoria-road, Old Charlton, Lieut.-Col. John Armstrong, L.R.C.P. & S. Irel., R.A.M.C. (retired).

Douglas.—On August 15th, at Adelaide, South Australia, Archibald Home Douglas, M.D., formerly residing in Edinburgh.

Evans.—On August 31st, at Rosslyn-hill, Hampstead, N.W., suddenly, William Norman Evans, M.R.C.S. Eng., L.R.C.P. Lond.

Griffin.—On August 21st, Montagu Laurence Griffin, M.B., B.Ch., B.A.O. Dub., of Plymouth, aged 64.

Gulland.—On Sept. 4th, at Malvern Hill House, Cheltenham, Alexander Dudgeon Gulland, Surgeon-General, M.D. Edin., in his 91st year.

Horne.—On Sept. 5th, at Merrion-square, Dublin, Sir Andrew John Horne, F.R.C.P. Irel., aged 68.

Murray.—On Sept. 2nd, at Aberdeen, John Murray, M.B. C.M. Aberd., Lieutenant-Colonel, A.M.D., of Mastrick and Ashburn-gardens, S.W., in his 82nd year.

Needham.—On Sept. 6th, at Bournemouth, Frederick Needham, M.D. St. And., M.R.C.P. Edin., M.R.C.S. Eng., L.S.A., late Commissioner of the Board of Control, aged 88.

Paterson.—On Sept. 2nd, very suddenly, at Buncrana, Co. Donegal, Ireland, William Bromfield Paterson, F.R.C.S. Eng., L.D.S., of Manchester-square, London, W., aged 63.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

The Manager of The Lancet would like to purchase copies of the issue of Feb. 2nd, 1924, for which subscribers may have no further use. He will be pleased to pay 1s. each for them. Such copies should be addressed to him at 423, Strand, London, W.C. 2.

Notes, Comments, and Abstracts.

LABORATORY FACILITIES UNDER THE NATIONAL HEALTH INSURANCE.

By T. Lister Croft, LL.B.,

SECRETARY, MEDICAL AND PANEL COMMITTEE, WEST RIDING OF YORKSHIRE.

At the recent British Medical Association Conference held in Bradford the Medical Sociology Section discussed the question, "Has the National Insurance Act justified its existence?" One of the speakers, Dr. G. B. Hillman, of Wakefield, dealing with the question from the general practitioner's point of view, referred to the West Riding Scheme for Laboratory Facilities as an instance of progressive action on the part of panel committees. This statement has created some inquiry as to the scope and character of this scheme, and the following particulars may be of interest. It would be more correct to refer to these facilities as an arrangement with the Public Health Department of the West Riding County Council rather than as a fully matured scheme.

The question of laboratory facilities was first raised by the West Riding Panel Committee in 1919. The County Council were at the time rendering quite voluntary assistance to the general practitioners in the area by the examination of specimens, but no definite arrangement was in force. It was felt by the Panel Committee that something more was required. The question was discussed and considered, and ultimately the following resolution was passed:—

"That in the opinion of this Committee the time has arrived when laboratory facilities should be provided in the West Riding for the more scientific investigation of disease than is possible with the facilities at present available."

A copy of this resolution was sent to the West Riding Insurance Committee and also to the Ministry of Health, and the resolution was subsequently approved by the West Riding Insurance Committee, who intimated such approval to the West Riding County Council and the Ministry of Health.

A subcommittee continued to work on the matter for some time, and ultimately presented the following suggested scheme which was approved and adopted by the Panel Committee.

Suggested Scheme.

1. That every insured person should have access through his or her doctor to every kind of laboratory examination and vaccine treatment which the doctor considers he or she needs for the proper treatment of any illness.
2. That every panel doctor should have access to the laboratory and the right of consultation with the bacteriologist on any specific matter referred by the former to the latter.
3. That laboratory facilities should be given as an "additional benefit."
4. That the most satisfactory arrangement would be the provision and maintenance of a laboratory equipped with staff and all needful requirements, but—failing this—that an arrangement should be made with some one or more laboratories at present existing for the work to be done at a definite scale of fees.
5. That in the event of a separate laboratory being created—(*a*) small stocks of outfits (for urgent cases) should be distributed amongst representative doctors (such as members of the local medical committee) for supply to doctors on application; (*b*) that the advice and aid of the bacteriologist should, as far as possible, be available to doctors for demonstrating methods difficult in technique (such as lumbar punctures, &c.).
6. That if existing laboratories are utilised some such arrangement as in 5 (*a*) be made with the contracting laboratory.

Staff Required.—One well-qualified and specialised bacteriologist; one unqualified laboratory assistant; one (part-time) cleaner or caretaker. Approximate initial cost, £1100. Approximate annual cost, £2500 to £3000.

This scheme has never operated, as it was unfortunately brought forward at a time when it could not possibly be financed. It is interesting to note that so far as the West Riding, with its population of 500,000 is concerned, the cost would not run to more than 1½*d*. per insured person per annum.

Eventually, as a result of the Panel Committee's resolution and other circumstances which arose, a conference was arranged between the Panel Committee and the West Riding Public Health Committee. At this conference the Panel Committee stated that its reason for bringing forward the question and formulating the scheme arose from the urgent necessity for suitable laboratory facilities being provided for obtaining adequate scientific treatment in all cases. They pointed out that the health of the individual resulted in the general health and well-being of the community. The county authorities stated that they had every desire to help the general practitioner, and expressed themselves as willing and anxious to meet the position by

A SERIES of eight lectures will be given this autumn by members of the lecturing staff of the People's League of Health on the Mind and What We Ought to Know About It. These will be delivered at the Medical Society's headquarters, 11, Chandos-street. Cavendish-square. W. 1. beginning on Monday, Oct. 20th. at 6 P.M., and continuing on subsequent Monday evenings till Dec. 8th. The lectures will be delivered by Dr. Bernard Hart, Dr. Thomas Beaton. Dr. R. G. Rows, Sir Maurice Craig. Sir Robert Armstrong-Jones, Sir Frederick Mott, Dr. W. A. Potts, Dr. A. F. Tredgold. A syllabus of the course will be sent on application to the hon. organiser, 12, Stratford-place, London, W. 1.

ROYAL INFANT ORPHANAGE, WANSTEAD.—The next half-yearly election for the *admission of fatherless* children to the orphanage at Wanstead, E. 11, will be held in November. Children under 7 years of age are eligible, and applications for information and nomination papers should be addressed to the secretary at the orphanage.

MEMORIAL TO THE LATE MR. NEWBOLT.—A brass tablet to the memory of the late Mr. G. P. Newbolt, surgeon of Liverpool, was unveiled by the Lord Mayor of Liverpool on Sept. 4th at Leasowe Hospital for Crippled Children. The wording on the memorial tablet reads: "In gratitude to God for the memory of George Palmerston Newbolt. C.B.E.. F.R.C.S., First Chairman of the Medical Board of this Hospital. A great surgeon, a lover of children, a faithful servant of his fellow men. 'His name a great example stands.'"

THE LATE DR. T. MCCRAITH FOLEY.—Thomas McCraith Foley, L.R.C.P. & S. Irel., who died recently at Scarborough. was medical officer to the Union Infirmary of that town. He was a son of the late Rev. Patrick Foley, of Kilscoran. Co. Wexford. Ireland, and qualified in medicine in 1887. After some experience as a ship's surgeon, including service on the Sultan of Morocco's yacht. he started practice in Scarborough about 30 years ago, and took an active interest in municipal affairs. He was a member of the Scarborough town council and acted for a time as chairman of the health subcommittee of the council. He was connected with the 5th Yorkshire Regiment (Territorials) for many years and retired with the rank of surgeon-colonel. During the war, from 1914 to 1917. he was attached to the R.A.M.C. Dr. Foley is survived by his widow.

THE LATE DR. W. NORMAN EVANS.—William Norman Evans, M.R.C.S., L.R.C.P.Lond., who died recently as the result of a sudden heart attack, at his residence at 43, Rosslyn-hill. Hampstead, in his sixtieth year, was a member of a family which has been associated with Hampstead for 150 years. He was the sixth in uninterrupted succession to practise medicine in the borough. His father was Herbert Norman Evans, M.B. Oxf., of Hampstead House, Seaford, Sussex, to whose practice in Thurlow-road he succeeded about 30 years ago. He received his medical education at St. Bartholomew's Hospital, qualifying in 1887. He was for some years Surgeon-Captain of the 19th Middlesex R.V., commanded the 5th London Volunteer Infantry Brigade Bearer Company, and was formerly the medical officer of the Cripples' and Incurables' Home for Children at Hampstead. At the time of his death he was senior medical officer of the Hampstead Provident Dispensary. He had been in partnership with Dr. W. E. Hills, of Church Row, since 1903. Dr. Evans leaves a widow and two daughters.

MEMORIAL TO THE LATE SIR WILLIAM MACEWEN.—At a meeting held in the Hall of the Royal Faculty of Physicians and Surgeons, Glasgow, on May 22nd and reported in THE LANCET (May 31st, 1924, p. 1133), it was resolved to promote a fitting memorial to the life and work of the late Sir William Macewen. The meeting was a full and enthusiastic one, and a strong general committee was formed, as well as an executive representative of the different interests, both committees being given power to add to their number. It was decided, as the result of several meetings which have been held since, that the fund to be collected shall be applied to three main purposes, in the following order: (1) The provision of a bronze bust of Sir William Macewen, by Mr. G. H. Paulin, to be placed in the University, and a replica for Lady Macewen; (2) the establishment of a memorial lecture to be known as "The Sir William Macewen Lecture," to be delivered annually or biennially, dealing with any branch or aspect of surgical science; (3) the foundation of a Macewen medal or prize in surgery, to be awarded annually. It has not been decided yet whether this shall be assigned to the class of surgery at Glasgow University or shall be given a wider application. It is proposed to aim at the collection of a fund amounting to £3000, towards which a number of subscriptions, varying from £1 1s. to £100, have already been received. Intending subscribers should communicate with the hon. treasurer, Mr. James Macfarlane. D.L., LL.D., Wesleyan-st., Glasgow, S.E.

Messrs. Ernest Benn announce the forthcoming publication of "The Chemistry of the Blood in Clinical Medicine," by Dr. C. L. V. De Wesselow, chemical pathologist to St. Thomas's Hospital; and "Practical Surgery Illustrated," by Victor Pauchet, translated by F. R. H. Atkinson, M.D., with a special introduction by Sir Charles Gordon Watson, F.R.C.S.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.—A post-graduate course will be held from Oct. 6th to Nov. 28th, consisting of the following subjects: out-patient clinics, clinical lectures and demonstrations; lectures on the anatomy and physiology of the nervous system; lectures on the pathology of the nervous system; clinical demonstrations *on* methods of examination. Copies of the syllabus may be obtained from Dr. J. G. Greenfield. Dean of the Medical School, at the Hospital, Queen-square, Bloomsbury, London. W.C. 1.

DANGEROUS DRUGS ORDER.—The wording of the conditions attached to the Order made on August 15th, 1921, under the Dangerous Drugs Act. 1920, *for the* exemption of certain hospitals and other institutions from the Dangerous Drugs Regulations. was found in certain respects to impose restrictions on medicine which did not themselves come within the scope of these Regulations. In order to make it clear that such substances *are not* to be regarded as subject to the conditions attached to the Order, the Home Secretary has now added to both Schedule I. and Schedule II. a new condition, which runs: "Nothing in this Schedule shall affect any medicine or other substance to which the Regulations do not apply." The alteration has been effected by the issue of a new Order (H.M. Stationery Office, 1*d.*), entitled the "Dangerous Drugs (Hospital General Exemption) Order (1924)," which replaces the Order of August 15th, 1921. Apart from the change of wording needed to correct the misunderstanding, this Order differs only in verbal points from the former Order.

Appointments.

BENTHAM, ETHEL, M.D. Brux., has been nominated by the Minister of Health to be a Member of the Metropolitan Asylums Board.

DORMER, P. A., M.D. Dub., B.A.O., D.P.H., has been appointed Medical Officer of Health for Jarrow.

DUNLOP, A. G., Certifying Surgeon under the Factory and Workshop Acts for the Worksop District of the County of Nottingham.

NEGUS, V. E., M.S. Lond., F.R.C.S. Eng., Junior Surgeon for Diseases of the Throat and Nose at King's College Hospital.

SINCLAIR, JAMES DONALD, M.R.C.S. Eng., L.R.C.P. Lond., to be one of the Medical Referees under the Workmen's Compensation Act, 1906, for the districts of the Barnard Castle, Darlington, Richmond County Courts (Circuit No. 2), and the Leyburn and Northallerton County Courts (Circuit No. 15).

STANTON, W. E., L.M.S.S.A. Lond., Certifying Surgeon under the Factory and Workshop Acts for the Market Deeping District of the County of Lincoln.

WOOD, DOROTHY, M.R.C.S. Eng., L.R.C.P. Lond., House Surgeon to the New Sussex Hospital for Women and Children, Brighton.

The Devon Royal Mental Hospital, Exminster: SOLLY, R. V., M.D., B.S. Lond., M.R.C.P. Lond., F.R.C.S. Eng., Consulting Pathologist: MUIR, D. MILLER, M.R.C.S. Eng., L.R.C.P. Lond., D.M.R. & E., Consulting Radiologist: LOCK, NORMAN F., F.R.C.S. Eng., M.B., Ch.B., L.R.C.P. Lond., Consulting Surgeon: ACKLAND, J. M., M.R.C.S. Eng., L.D.S., Consulting Dental Surgeon: HAWKES, G. P. D., M.D., B.C. Camb., Consulting Ophthalmic Surgeon.

Vacancies.

For further information refer to the advertisement columns.

Barnsley, Beckett Hospital and Dispensary.—H.P. £120.

Barnsley County Borough.—Asst. M.O.H. and Asst. Sch. M.O. £600.

Birkenhead County Borough.—Asst. M.O. £150, res.

Bradford Royal Infirmary.—Two H.S.'s and one H.P. Each £150.

Central London Ophthalmic Hospital, Judd-street, St. Pancras, W.C.—H.S. £100. Also Jun. H.S. £50.

Evelina Hospital for Children, Southwark, S.E.—H.P. £120.

Hospital for Epilepsy and Paralysis, Maida Vale, W.—Med. Reg. £100.

Hospital for Sick Children, Great Ormond-street, W.C.—H.S. £50.

Hull, Victoria Hospital for Sick Children.—H.P. £100.

Leeds City.—Asst. Clin. Tuberculosis O. £600.

Liverpool University.—Prof. of Anatomy. £800.

London Lock Hospital, 91, Dean-street, W.—H.S. £200.

Manchester, St. Mary's Hospitals.—Four H.S.'s. Each £50.

Miller General Hospital for South-East London, Greenwich-road, S.E.—Hon. M.O. for Skin Dept.

National Hospital for Diseases of the Heart, Westmoreland-street, W.—M.O. for Out-patients. £125. Phys to Out-patients.

Northampton General Hospital.—Hon. P.

Norwich, Norfolk and Norwich Hospital.—Cas. O. and H.S. £150.

Nottingham General Dispensary.—Res. S. £250.
Pietermaritzburg, S. Africa, Grey's Hospital.—H.S. £400.
Plymouth, South Devon and East Cornwall Hospital.—H.S. and H.P. £100 and £50 respectively.
Prince of Wales's General Hospital, Tottenham, N.—H.S.'s, H.P., Each £150. Also Jun. H.S. and H.P. Each £110.
Queen's Hospital for Children, Hackney-road, E.—H.S. £100.
Royal Ear Hospital, Dean-street, Soho.—Reg. £50.
Royal Free Hospital, Gray's Inn-road, W.C.—Med. Reg.
Royal National Orthopædic Hospital, 234, Great Portland-street, W.—Two H.S's. Each £150.
Royal Naval Medical Service.—Surg. Lieuts. 25*s.* per day.
St. Marylebone General Dispensary, 30, Marylebone-lane, W.—Hon. P.
St. Marylebone Hospital, Ladbroke-grove, W.—Third Asst. M.O. £300.
St. Peter's Hospital for Stone, Henrietta-street, Covent Garden, W.C.—H.S. £75.
Seamen's Hospital Society, Greenwich.—H.S. for Albert Dock Hospital. Also H.P. and H.S. at Dreadnought Hospital. Each £150.
Shanghai Municipal Council, Public Health Department.—Asst. Path. £1250.
Sheffield Royal Infirmary.—Res. Surg. O. £200.
South London Hospital for Women, Clapham Common, S.W.—H.P. and three H.S.'s. Each £50.
West London Hospital, Hammersmith-road, W.—H.P. and two H.S.'s. Each £100.
Winchester, Royal Hampshire County Hospital.—H.P. £150.

The Chief Inspector of Factories, Home Office, London, S.W. announces a vacant appointment at Kirkwall, Orkney.

Births, Marriages, and Deaths.

BIRTHS.

BARRY.—On August 31st, at The Chestnuts, Roos, E. Yorks. the wife of J. H. Barry, L.R.C.P. & S. Irel., of a son.

BASTIAN.—On Sept. 5th, at St. David's-road, Southsea, the wife of Surgeon-Commander W. Bastian, R.N., H.M.S. *Dryad*, of a daughter.

HADFIELD.—On August 31st, at "The Red House," Beaconsfield, the wife of J. A. Hadfield, M.B., Ch.B. Edin., of a son.

MARKS.—On Sept. 3rd, at Inverness-terrace, Hyde Park, the wife of Maurice J. Marks, L.D.S. R.F.P.S. Glasg., of a son.

MCELLIGOTT.—On Sept. 6th, at 177, Westmount-road, Eltham, S.E.9, to Dr. Geraldine, wife of Dr. E. T. McElligott—a son.

REICHWALD.—On Sept. 1st, at Timber Hill, Ashtead, Surrey, the wife of Dr. M. B. Reichwald, M.B., B.S. Lond., of a daughter.

STOCKER.—On Sept. 2nd, at Glebe Croft, Bakewell, the wife of Major C. J. Stocker, M.D. Camb., I.M.S., of a son.

MARRIAGES.

WILSON—CURJEL.—At Christ Church, Simla, on the 16th August, 1924, by the Revd. C. H. Hemming, William Robert Wilson, Indian Civil Service, to Dagmar F. Curjel, M.D. Glasg., D.P.H. Camb., Assistant to the Inspector-General of Civil Hospitals, Punjab.

WOOD—WOLSELEY.—On Sept. 6th, at St. Stephen's, Twickenham, Edward Archer Wood, L.R.C.P. Lond., M.R.C.S. Eng., L.S.A., Dulwich, to Minnie Bathurst Wolseley, daughter of Henry John Wolseley, M.B., C.M. Edin., and Mrs. Wolseley, also of Dulwich.

DEATHS.

ALLEN.—On August 30th, at Swaffham, Norfolk, Vernon Francis Allen, L.R.C.P. & S. Edin., aged 58.

ARMSTRONG.—On August 31st, at Victoria-road, Old Charlton, Lieut.-Col. John Armstrong, L.R.C.P. & S. Irel., R.A.M.C. (retired).

DOUGLAS.—On August 15th, at Adelaide, South Australia, Archibald Home Douglas, M.D., formerly residing in Edinburgh.

EVANS.—On August 31st, at Rosslyn-hill, Hampstead, N.W., suddenly, William Norman Evans, M.R.C.S. Eng., L.R.C.P. Lond.

GRIFFIN.—On August 21st, Montagu Laurence Griffin, M.B., B.Ch., B.A.O. Dub., of Plymouth, aged 64.

GULLAND.—On Sept. 4th, at Malvern Hill House, Cheltenham, Alexander Dudgeon Gulland, Surgeon-General, M.D. Edin., in his 91st year.

HORNE.—On Sept. 5th, at Merrion-square, Dublin, Sir Andrew John Horne, F.R.C.P. Irel., aged 68.

MURRAY.—On Sept. 2nd, at Aberdeen, John Murray, M.B. C.M. Aberd., Lieutenant-Colonel, A.M.D., of Mastrick and Ashburn-gardens, S.W., in his 82nd year.

NEEDHAM.—On Sept. 6th, at Bournemouth, Frederick Needham, M.D. St. And., M.R.C.P. Edin., M.R.C.S. Eng., L.S.A., late Commissioner of the Board of Control, aged 88.

PATERSON.—On Sept. 2nd, very suddenly, at Buncrana, Co. Donegal, Ireland, William Bromfield Paterson, F.R.C.S. Eng., L.D.S., of Manchester-square, London, W., aged 63.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

THE Manager of THE LANCET would like to purchase copies of the issue of Feb. 2nd, 1924, for which subscribers may have no further use. He will be pleased to pay 1s. each for them. Such copies should be addressed to him at 423, Strand, London, W.C. 2.

Notes, Comments, and Abstracts.

LABORATORY FACILITIES UNDER THE NATIONAL HEALTH INSURANCE.

BY T. LISTER CROFT, LL.B.,
SECRETARY, MEDICAL AND PANEL COMMITTEE, WEST RIDING OF YORKSHIRE.

AT the recent British Medical Association Conference held in Bradford the Medical Sociology Section discussed the question, "Has the National Insurance Act justified its existence?" One of the speakers, Dr. G. B. Hillman, of Wakefield, dealing with the question from the general practitioner's point of view, referred to the West Riding Scheme for Laboratory Facilities as an instance of progressive action on the part of panel committees. This statement has created some inquiry as to the scope and character of this scheme, and the following particulars may be of interest. It would be more correct to refer to these facilities as an arrangement with the Public Health Department of the West Riding County Council rather than as a fully matured scheme.

The question of laboratory facilities was first raised by the West Riding Panel Committee in 1919. The County Council were at the time rendering quite voluntary assistance to the general practitioners in the area by the examination of specimens, but no definite arrangement was in force. It was felt by the Panel Committee that something more was required. The question was discussed and considered, and ultimately the following resolution was passed:—

"That in the opinion of this Committee the time has arrived when laboratory facilities should be provided in the West Riding for the more scientific investigation of disease than is possible with the facilities at present available."

A copy of this resolution was sent to the West Riding Insurance Committee and also to the Ministry of Health, and the resolution was subsequently approved by the West Riding Insurance Committee, who intimated such approval to the West Riding County Council and the Ministry of Health.

A subcommittee continued to work on the matter for some time, and ultimately presented the following suggested scheme which was approved and adopted by the Panel Committee.

Suggested Scheme.

1. That every insured person should have access through his or her doctor to every kind of laboratory examination and vaccine treatment which the doctor considers he or she needs for the proper treatment of any illness.

2. That every panel doctor should have access to the laboratory and the right of consultation with the bacteriologist on any specific matter referred by the former to the latter.

3. That laboratory facilities should be given as an "additional benefit."

4. That the most satisfactory arrangement would be the provision and maintenance of a laboratory equipped with staff and all needful requirements, but—failing this—that an arrangement should be made with some one or more laboratories at present existing for the work to be done at a definite scale of fees.

5. That in the event of a separate laboratory being created—(*a*) small stocks of outfits (for urgent cases) should be distributed amongst representative doctors (such as members of the local medical committee) for supply to doctors on application; (*b*) that the advice and aid of the bacteriologist should, as far as possible, be available to doctors for demonstrating methods difficult in technique (such as lumbar punctures, &c.).

6. That if existing laboratories are utilised some such arrangement as in 5 (*a*) be made with the contracting laboratory.

Staff Required.—One well-qualified and specialised bacteriologist; one unqualified laboratory assistant; one (part-time) cleaner or caretaker. Approximate initial cost, £1100. Approximate annual cost, £2500 to £3000.

This scheme has never operated, as it was unfortunately brought forward at a time when it could not possibly be financed. It is interesting to note that so far as the West Riding, with its population of 500,000 is concerned, the cost would not run to more than 1½*d.* per insured person per annum.

Eventually, as a result of the Panel Committee's resolution and other circumstances which arose, a conference was arranged between the Panel Committee and the West Riding Public Health Committee. At this conference the Panel Committee stated that its reason for bringing forward the question and formulating the scheme arose from the urgent necessity for suitable laboratory facilities being provided for obtaining adequate scientific treatment in all cases. They pointed out that the health of the individual resulted in the general health and well-being of the community. The county authorities stated that they had every desire to help the general practitioner, and expressed themselves as willing and anxious to meet the position by doing all laboratory work as far as they possibly could and not limiting the work to so-called public health work.

The Panel Committee emphasised its desire that ultimately an additional medical benefit should be established and financed in the form of "laboratory benefit" for all insured persons. In the meantime, on behalf of the general practitioners, the Panel Committee gratefully accepted the proposed extended use of the County Laboratory and expressed the hope that if and when laboratory benefits were established the working of any scheme in connexion therewith might be linked up with the County Laboratory.

The arrangements thus come to with the county authorities have been working since 1922 with most excellent and beneficial results. Under these arrangements panel practitioners in the West Riding are able to obtain the infinite variety of bacteriological investigations—including the preparation of vaccines—which the modern practice of medicine renders so essential for the efficient treatment of their patients.

The West Riding Panel Committee are, however, still pushing forward their views. They have brought their proposed scheme to the notice of the Ministry of Health and one of the largest approved societies, and it is their intention to see that the need for full laboratory facilities for every insured person throughout the country is brought to the notice of the coming Royal Commission.

In the meantime, the annual conference of Panel Committees, held in October, 1923, have approved the following resolution brought forward by the West Riding Panel Committee :—

> "That it is essential for the satisfactory treatment of diseases occurring amongst insured persons that a full and complete laboratory service should be established in every area, and that the Insurance Acts Committee should be requested to take all necessary steps to ensure that such a service should be established at the earliest possible moment."

The annual conference of 1922 had already given support to some such scheme on the motion of a leading representative of a Yorkshire insurance committee.

SOME FURTHER SINS OF CIVILISATION.

To show that the vis medicatrix naturæ is coming to the front in practice and treatment of disease, we have only to instance the vogue of heliotherapy and of the return to more natural conditions as regards diet. There are, however, many other practices of daily life in which we have strayed from the early and presumably saner customs of the race, and Dr. C. W. Laver, of Western Australia, writes to us on the disadvantages to health entailed in our present mode of performing the act of defæcation. He states his conviction that the cardinal and sole factor in the causation of appendicitis is our artificial and unnatural posture in defæcation and in contradistinction to the squatting position for the following reasons. First, the box seat posture defeats correct direction of expulsion of excrement; secondly, it defeats gravitation ; thirdly, it defeats the free power of the expelling muscles ; and, fourthly, it defeats the support of the thighs to the abdominal walls and protection of the appendix. He also holds that constipation, the most common perhaps of our modern ills, is due to using the unnatural artificial method which causes abdominal strain. These reasons find their application in the causation of appendicitis through the forcing of fæcal matter from the intestinal canal into the appendix, and, further, the absence of protection of the thighs on the inguinal canal he considers an important causal factor in inguinal hernia.

CANAL CHILDREN.

CANAL boat children have for some time past been objects of solicitude in regard to their health and education. During the year April 1st, 1923, to March 31st, 1924, the chief inspector of the National Society for the Prevention of Cruelty to Children found[1] 225 children on canal boats, of whom 76 had been born there. Out of this number 158 were still under school age, and only 23 children—eight of them under 12 years of age—were seen at work on the boats. This great improvement on previous years is ascribed by the chief inspector to the work of the Society. It should, of course, be remembered that a departmental committee appointed by Dr. Addison in 1920 decided to prohibit children of school age from living on the boats during term time; this committee thought that in the long run the women, too, would leave the boats. The recent strike afforded the chief inspector opportunity of conversation with boatmen, when he found that the majority were in favour of leaving both women and children off the boats and working them by men only. While the average figures show no overcrowding on the standard of the Canal Boat Act, the chief inspector says that overcrowding does exist on a number of boats. Most of the one-cabin boats are registered for three adults, or two adults and two children under 12 years; in two-cabin boats registered for two adults and five children, the tendency is for the whole family to occupy one cabin only. Six fatal accidents to children occurred during the year, five by drowning and one by scalding; one girl of 7 years has fallen into the canal three times, and a boy of 11, already rescued 16 times, was nearly drowned last year. From the point of view of education, the exclusion of children from the canal boats, which is fast becoming an accomplished fact, is to be welcomed. As far as health is concerned they compare favourably with town children, the freedom of the daytime compensating for the narrow, unventilated cabins at night; the incidence of infectious disease has been slight. But it is evident that as time goes on there will remain little canal boat inspection for the Society to do.

UNSIGHTLY WARTS.

To the Editor of THE LANCET.

SIR,—Referring to Dr. G. S. Sander's request for advice as to the treatment of small, multiple soft warts on the back of the hand (THE LANCET, August 2nd, p. 256), I beg to say that I have successfully treated many such cases with liquor ferri perchloridi fort, B.P., as an escharotic, by carefully applying it with a small, blunt-pointed glass rod, avoiding the skin around the bases of the warts.—I am, Sir, yours faithfully,

Jamaica, August 22nd. A. J. SALMON, M.D., C.M. Camb.

A DAY-BOOK AND LEDGER COMBINED.

THE "One Entry Medical Account Book" (London H. K. Lewis and Co., Ltd.) consists of cover and four quarterly insets (complete 20*s.*, insets 3*s.* 6*d.* each, cover 6*s.*), and provides a simple method for the practitioner who has little time to devote to this side of his work. It will serve him to some extent to ascertain his financial position by means of a total easily available at the end of his financial year. The cost, however, seems a little high for the restricted scope of the book.

Stethoscope would like to know of some place along the French or Italian Riviera which would be suitable for a case of rheumatic arthritis (lady) and where the charges would be moderate. A place neither too gay nor too dull preferred.

Medical Diary.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE
MEDICAL ASSOCIATION, 1, Wimpole-street, London, W.
MONDAY, Sept. 15th, to SATURDAY, Sept. 20th.—ROYAL
WESTMINSTER OPHTHALMIC HOSPITAL, Charing Cross.
Clinical Instruction every afternoon from 2 P.M.
Wed., 5 P.M., Mr. Gimblett: Clinical Demonstration
on Common Affections of the Eye. Thurs., 5 P.M.,
Mr. Morgan: Fundus Class. Fri., 10 A.M., Mr. Hine:
Methods of Examination.—INFANTS HOSPITAL, Vincent-
square, Westminster. Mon., 2 P.M., Dr. W. E. Robinson:
O.P., Cases of Malnutrition. 3 P.M., Dr. Nora Schuster:
Demonstration, Chemical Examination of the Blood.
4 P.M., Mr. Tyrrell Gray: Lecture, Pyloric Stenosis.
Tues., 2 P.M., Dr. Eric Pritchard: O.P., Feeding Cases.
3 P.M., Dr. Caroline Maule: Demonstration, the
Schick Test, &c. 4 P.M., Mr. Philip Franklin: Chronic
Nasal Discharge and Sinusitis in Children. Wed.,
2 P.M., Dr. Helen Mackay: O.P., Cases of Birth Injury.
3 P.M., Dr. Eric Pritchard: Demonstration, the
Modification of Cow's Milk. 4 P.M., Dr. Donald Paterson:
Lecture, Infections of the Urinary Tract. Thurs.,
2 P.M., Dr. Donald Paterson: O.P., Types of Diarrhœa.
3 P.M., Dr. Eric Pritchard: Demonstration, Stools.
4 P.M., Dr. Helen Mackay: Lecture, Anæmia in Infancy
and Childhood. Fri., 2 P.M., Dr. Eric Pritchard and
Members of the Medical Staff: Round Table Consulta-
tion. 4 P.M., Dr. Donald Paterson: Cyclic Vomiting.
Sat., 3 P.M., Visit to St. Margaret's Hospital for
Ophthalmia Neonatorum.

WEST LONDON POST-GRADUATE COLLEGE, West
London Hospital, Hammersmith, W.
MONDAY, Sept. 15th.—11 A.M., Surgical Registrar: Surgical
Wards. 12 noon, Mr. Simmonds: Applied Anatomy.
2 P.M., Mr. Addison: Surgical Wards.
TUESDAY.—11 A.M., Dr. McDougal: Electrical Dept.
12 noon, Dr. Burrell: Chest Cases. 2 P.M., Mr. Sinclair:
Surgical Out-patients.
WEDNESDAY.—10 A.M., Dr. Saunders: Medical Diseases of
Children. 2 P.M., Dr. Owen: Medical Out-patients.
2.30 P.M., Mr. Donald Armour: Surgical Wards.
THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological
Dept. 2 P.M., Mr. MacDonald: Genito-Urinary Dept.
2 P.M., Mr. Simmonds: Surgical Out-patients.
FRIDAY.—10 A.M., Mr. Dudley Buxton: Dental Dept.
2 P.M., Dr. Burrell: Medical Out-patients. 2 P.M.,
Mr. Vlasto: Throat, Nose, and Ear Dept.
SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy.
10 A.M., Dr. Saunders: Medical Diseases of Children.
10 A.M., Mr. Banks-Davis: Operations on Throat,
Nose, and Ear.
Daily 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M.,
In-patients, Out-patients, Operations, Special Depart-
ments.

[1] Annual Report, 1923-24. Victory House, Leicester-sq., W.C.

The Montgomery Lecture

ON THE

EVOLUTION OF THE PUPILLARY REACTIONS.

Delivered at the Royal College of Surgeons in Ireland

BY E. TREACHER COLLINS, F.R.C.S. ENG.,
CONSULTING SURGEON, ROYAL LONDON OPHTHALMIC HOSPITAL, AND OXFORD EYE HOSPITAL.

REGARDING knowledge of the biological evolution of a vital phenomenon as essential for the study of its manifestation in man, I have collected observations from various sources regarding the pupillary reactions in animals, in the endeavour to investigate the upgrowth of their mechanism.

In 1890, being desirous of examining the arrangement of the pigment epithelial cells in the uveal tract, I introduced a method of depigmenting microscopical sections of the eye by means of chlorine water and a weak solution of hydrochloric acid, which I described in the Royal London Ophthalmic Hospital Reports for December of that year. Since that time several improved methods of bleaching sections have been adopted. That most usually employed now is Alfieri's method with permanganate of potash and oxalic acid. By such depigmentation several new anatomical points in connexion with the histology of the iris and ciliary body have been discovered. By it Henry Juler and John Griffiths[1] were able to demonstrate, in 1894, the presence of dilator contractile fibres in the nucleated layer at the back of the iris, immediately in front of the posterior layer of pigmented cubical epithelial cells.

DEVELOPMENT OF MUSCLE FIBRES OF THE IRIS.

It was by bleaching sections that Grynfeltt[2] in 1899, Heerfordt[3] in 1900, and Forsmark[4] in 1905, proved that Bruch's membrane in the iris is formed of fibres derived from cells in the outer layer of the secondary optic vesicle.

It was shown that these cells are at first cylindrical or cuboid, and contain nuclei at or near their centres, and that later the anterior part of each cell is differentiated by the outgrowth of a contractile fibre, while the nucleus and the pigment are displaced towards the posterior end. The fibres blend to form the dilator muscle of the iris, which is, therefore, an epithelial structure.

The researches of Nussbaum[5] in 1899, and of Szili[6] in 1901, showed that the sphincter muscle of the iris, like the dilator, originates from the anterior layer of the pigment epithelium on its posterior surface, starting at the point where it folds backwards to become the posterior layer.

The sphincter appears first as a group of nuclei which soon extends in the direction towards the ciliary border of the iris, its cells assuming the spindle-shape and remaining for a time closely connected with the anterior epithelium. About the fifth month, in the human fœtus, connective tissue from the iris stroma begins to insert itself between the sphincter and the epithelium, from the outer side, and a month later the muscle is divided by septa of connective tissue into two or three parts. At birth the sphincter still lies to a large extent upon the epithelium and remains united with it at the pupil margin. Sphincter and dilator therefore are both epithelial structures springing from the same layer of cells. They are connected with each other by numerous fibres of the same nature as themselves.

More recently, in 1922, Holth and Berner,[7] by bleaching sections of the iris, have proved that cases of congenital miosis are due to aplasia of the dilator muscle of the pupil.

A study of the morphology of the ciliary muscle in mammals shows that it is composed of spindle-shaped unstriated fibres, lying in spaces corresponding to those of the lamina supra-choroidea in the hinder part of the globe and to those of the ligamentum pectinatum anteriorly. The cells lining these lymphatic spaces are endothelial cells, and the ciliary muscle is formed by the proliferation and lengthening out of such endothelial cells into spindle-shaped cells. In the eyes of animals, and in pathological specimens of human eyes, cells are met with in the vicinity of the ciliary muscle fibres presenting transitional stages between endothelial cells and muscle cells. Cases have been recorded by Salzman and Fuchs in which muscle fibres have been met with in the lamina supra-choroidea, even as far back as the neighbourhood of the optic papilla. Evidently, therefore, the fibres of the ciliary muscle, unlike those of the iritic muscles, are mesoblastic in origin.

At first it seems strange that muscle fibres should be developed from cells of the neural epiblast, and that in two adjoining parts of the uveal tract—the iris and the ciliary body—which in the human eye are so frequently associated in their action, they should have been derived from different layers of the blastoderm. Here again I think a consideration of the morphology of the parts enables us to understand how this has come about.

DIRECT RESPONSE OF IRIS MUSCLE TO LIGHT IN SOME COLD-BLOODED VERTEBRATES.

It has been found that in amphibians and fishes light causes contraction of the pupil in the excised eye. The iris of an eel when cut out and placed in normal saline solution, contracts to the stimulus of light, which contraction seems to be due to direct action of light on its muscular fibres. The pigmented cells which compose the outer layer of the secondary vesicle, where it lies in contact with the retina, when stimulated by light manifest amœboid movements. They send out processes which protrude inwards between the outer segments of the rods and cones. Such movements are accompanied by currents in the fluid cell protoplasm, and migration of the long pigment particles into the processes from the body of the cell; they are very pronounced in fish and frogs and other cold-blooded animals.

Protoplasmic movement, the result of photic stimuli, is common in plants but comparatively rare in animals. It is met with in some of the lowest forms of animal life, in some fresh-water amœbæ, some hydra, and some of the ciliated infusoria. In the tissues of higher animals such movements have been retained only in the cells of the visual organs. It has been found that phototaxis in lowly developed organisms is chiefly, if not solely, brought about by rays of short wave-length, the blue, violet, and ultra-violet; which suggests that the real stimulus is chemical, not thermal in character, and similar to that produced by the action of light through chlorophyll in plants. That some chemical action is produced in the pigmented cells of the retina, by the action of light on them, is shown by their alkaline reaction being turned into an acid one, due probably to an oxidising process, the pigment granules in the cells, by the absorption of light, assisting in such changes of light-energy into protoplasmic movement.

In a fish's eye, like that of an eel, which has no ciliary body, the outer layer of cells developed from the secondary optic vesicle, where it ceases to line the retina, is continued directly on to the back of the iris. As those cells which line the retina have phototactic powers it is not surprising to find similar powers present in those which line the iris. Those which line the retina receive the stimulus of light on their inner surface, and protrude processes from it into the potential spaces between the rods and cones. Those lining the back of the iris receive the light stimulus on their outer surface which have processes proceeding from it, constituting the so-called membrane of Bruch, or dilator muscle of the iris. These cells of the outer layer of the secondary optic vesicle at the back of the iris lie flattened out against the stroma. Their processes do not project into it but run radially, so that when they become retracted in the dark the pupil dilates. The sphincter muscle is composed of spindle-shaped cells, which have budded off from the point of junction of the two layers of the secondary optic doing all laboratory work as far as they possibly could and not limiting the work to so-called public health work.

The Panel Committee emphasised its desire that ultimately an additional medical benefit should be established and financed in the form of "laboratory benefit" for all insured persons. In the meantime, on behalf of the general practitioners, the Panel Committee gratefully accepted the proposed extended use of the County Laboratory and expressed the hope that if and when laboratory benefits were established the working of any scheme in connexion therewith might be linked up with the County Laboratory.

The arrangements thus come to with the county authorities have been working since 1922 with most excellent and beneficial results. Under these arrangements panel practitioners in the West Riding are able to obtain the infinite variety of bacteriological investigations—including the preparation of vaccines—which the modern practice of medicine renders so essential for the efficient treatment of their patients.

The West Riding Panel Committee are, however, still pushing forward their views. They have brought their proposed scheme to the notice of the Ministry of Health and one of the largest approved societies, and it is their intention to see that the need for full laboratory facilities for every insured person throughout the country is brought to the notice of the coming Royal Commission.

In the meantime, the annual conference of Panel Committees, held in October, 1923, have approved the following resolution brought forward by the West Riding Panel Committee:—

"That it is essential for the satisfactory treatment of diseases occurring amongst insured persons that a full and complete laboratory service should be established in every area, and that the Insurance Acts Committee should be requested to take all necessary steps to ensure that such a service should be established at the earliest possible moment."

The annual conference of 1922 had already given support to some such scheme on the motion of a leading representative of a Yorkshire insurance committee.

SOME FURTHER SINS OF CIVILISATION.

To show that the vis medicatrix naturæ is coming to the front in practice and treatment of disease, we have only to instance the vogue of heliotherapy and of the return to more natural conditions as regards diet. There are, however, many other practices of daily life in which we have strayed from the early and presumably saner customs of the race, and Dr. C. W. Laver, of Western Australia, writes to us on the disadvantages to health entailed in our present mode of performing the act of defæcation. He states his conviction that the cardinal and sole factor in the causation of appendicitis is our artificial and unnatural posture in defæcation and in contradistinction to the squatting position for the following reasons. First, the box seat posture defeats correct direction of expulsion of excrement; secondly, it defeats gravitation; thirdly, it defeats the free power of the expelling muscles; and, fourthly, it defeats the support of the thighs to the abdominal walls and protection of the appendix. He also holds that constipation, the most common perhaps of our modern ills, is due to using the unnatural artificial method which causes abdominal strain. These reasons find their application in the causation of appendicitis through the forcing of fæcal matter from the intestinal canal into the appendix, and, further, the absence of protection of the thighs on the inguinal canal he considers an important causal factor in inguinal hernia.

CANAL CHILDREN.

CANAL boat children have for some time past been objects of solicitude in regard to their health and education. During the year April 1st, 1923, to March 31st, 1924, the chief inspector of the National Society for the Prevention of Cruelty to Children found[1] 225 children on canal boats, of whom 76 had been born there. Out of this number 158 were still under school age, and only 23 children—eight of them under 12 years of age—were seen at work on the boats. This great improvement on previous years is ascribed by the chief inspector to the work of the Society. It should, of course, be remembered that a departmental committee appointed by Dr. Addison in 1920 decided to prohibit children of school age from living on the boats during term time; this committee thought that in the long run the women, too, would leave the boats. The recent strike afforded the chief inspector opportunity of conversation with boatmen, when he found that the majority were in favour of leaving both women and children off the boats and working them by men only. While the average figures show no overcrowding on the standard of the Canal Boat Act, the chief inspector says that overcrowding does exist on a number of boats. Most of the one-cabin boats are registered for three adults, or two adults and two children under 12 years; in two-cabin boats registered for two adults and five children, the tendency is for the whole family to occupy one cabin only. Six fatal accidents to children occurred during the year, five by drowning and one by scalding; one girl of 7 years has fallen into the canal three times, and a boy of 11, already rescued 16 times, was nearly drowned last year. From the point of view of education, the exclusion of children from the canal boats, which is fast becoming an accomplished fact, is to be welcomed. As far as health is concerned they compare favourably with town children, the freedom of the daytime compensating for the narrow, unventilated cabins at night; the incidence of infectious disease has been slight. But it is evident that as time goes on there will remain little canal boat inspection for the Society to do.

UNSIGHTLY WARTS.

To the Editor of THE LANCET.

SIR,—Referring to Dr. G. S. Sander's request for advice as to the treatment of small, multiple soft warts on the back of the hand (THE LANCET, August 2nd, p. 256), I beg to say that I have successfully treated many such cases with liquor ferri perchloridi fort, B.P., as an escharotic, by carefully applying it with a small, blunt-pointed glass rod, avoiding the skin around the bases of the warts.—I am, Sir, yours faithfully,

Jamaica, August 22nd. A. J. SALMON, M.D., C.M. Camb.

A DAY-BOOK AND LEDGER COMBINED.

THE "One Entry Medical Account Book" (London H. K. Lewis and Co., Ltd.) consists of cover and four quarterly insets (complete 20*s.*, insets 3*s.* 6*d.* each, cover 6*s.*), and provides a simple method for the practitioner who has little time to devote to this side of his work. It will serve him to some extent to ascertain his financial position by means of a total easily available at the end of his financial year. The cost, however, seems a little high for the restricted scope of the book.

Stethoscope would like to know of some place along the French or Italian Riviera which would be suitable for a case of rheumatic arthritis (lady) and where the charges would be moderate. A place neither too gay nor too dull preferred.

Medical Diary.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, London, W.

MONDAY, Sept. 15th, to SATURDAY, Sept. 20th.—ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, Charing Cross. Clinical Instruction every afternoon from 2 P.M. Wed., 5 P.M., Mr. Gimblett: Clinical Demonstration on Common Affections of the Eye. Thurs., 5 P.M., Mr. Morgan: Fundus Class. Fri., 10 A.M., Mr. Hine: Methods of Examination.—INFANTS HOSPITAL, Vincent-square, Westminster. Mon., 2 P.M., Dr. W. E. Robinson: O.P., Cases of Malnutrition. 3 P.M., Dr. Nora Schuster: Demonstration, Chemical Examination of the Blood. 4 P.M., Mr. Tyrrell Gray: Lecture, Pyloric Stenosis. Tues., 2 P.M., Dr. Eric Pritchard: O.P., Feeding Cases. 3 P.M., Dr. Caroline Maule: Demonstration, the Schick Test, &c. 4 P.M., Mr. Philip Franklin: Chronic Nasal Discharge and Sinusitis in Children. Wed., 2 P.M., Dr. Helen Mackay: O.P., Cases of Birth Injury. 3 P.M., Dr. Eric Pritchard: Demonstration, the Modification of Cow's Milk. 4 P.M., Dr. Donald Paterson: Lecture, Infections of the Urinary Tract. Thurs., 2 P.M., Dr. Donald Paterson: O.P., Types of Diarrhœa. 3 P.M., Dr. Eric Pritchard: Demonstration, Stools. 4 P.M., Dr. Helen Mackay: Lecture, Anæmia in Infancy and Childhood. Fri., 2 P.M., Dr. Eric Pritchard and Members of the Medical Staff: Round Table Consultation. 4 P.M., Dr. Donald Paterson: Cyclic Vomiting. Sat., 3 P.M., Visit to St. Margaret's Hospital for Ophthalmia Neonatorum.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

MONDAY, Sept. 15th.—11 A.M., Surgical Registrar: Surgical Wards. 12 noon, Mr. Simmonds: Applied Anatomy. 2 P.M., Mr. Addison: Surgical Wards.

TUESDAY.—11 A.M., Dr. McDougal: Electrical Dept. 12 noon, Dr. Burrell: Chest Cases. 2 P.M., Mr. Sinclair: Surgical Out-patients.

WEDNESDAY.—10 A.M., Dr. Saunders: Medical Diseases of Children. 2 P.M., Dr. Owen: Medical Out-patients. 2.30 P.M., Mr. Donald Armour: Surgical Wards.

THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Dept. 2 P.M., Mr. MacDonald: Genito-Urinary Dept. 2 P.M., Mr. Simmonds: Surgical Out-patients.

FRIDAY.—10 A.M., Mr. Dudley Buxton: Dental Dept. 2 P.M., Dr. Burrell: Medical Out-patients. 2 P.M., Mr. Vlasto: Throat, Nose, and Ear Dept.

SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy. 10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations on Throat, Nose, and Ear.

Daily 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

---

[1] Annual Report, 1923-24. Victory House, Leicester-sq., W.C.

and by the stimulation of certain areas on the cerebral cortex. Parsons[9] found that electrical stimulation of the cortex of cats, dogs, and monkeys, in the neighbourhood of the crucial sulcus and over a considerable area of the occipital region, produced wide dilatation of the pupils when the cervical sympathetic nerves were intact, and a dilatation of about a half or two-thirds that amount when those nerves had been divided.

Dilatation of the pupil caused by section of the third nerve may be increased by stimulation of the cervical sympathetic; and cocaine, which acts by stimulation of the terminals of the cervical sympathetic, will cause a pupil dilated by atropine to enlarge still further. Fright, such as that produced by a sudden and unexpected noise, causes the pupils to dilate widely, even whilst the retina is being stimulated by exposure to bright light. Wide dilatation of the pupil enlarges the field of vision by allowing rays of light to pass into the eye which, owing to their obliquity, would otherwise be cut off. Such an enlargement of the field of vision is of considerable importance to those animals which require a large range of circumferential vision to warn them of the approach of danger. In most of the ungulata, whose safety mainly depends on their rapidity of flight, an increased range of circumferential vision is further provided for by horizontally oval-shaped pupils.

Stimulation of the cervical sympathetic nerve, besides exciting into action the dilator muscle fibres of the iris, causes contraction of the two sets of unstriated muscle fibres in the orbit described by Müller—viz., that which causes widening of the palpebral fissure by retraction of the upper eyelid, and that which causes protrusion of the eyeball. An enlargement of the palpebral fissure and an increased prominence of the eyeball, like dilatation of the pupil, serve to increase the range of vision; the three symptoms are characteristic of fright. It seems, therefore, most probable that they have all three been evolved for the same purpose—that is, to enable animals to perceive and escape quickly from approaching foes.

The instinct of flight, which is usually evoked by the emotion of fear, may be called into action in different ways. The stimulus may be received through the auditory nerve from some sudden and unexpected sound; through the optic nerve by the perception of some approaching danger; or through the cutaneous surface by the sensation of pain. In whichever way elicited the fibres of the cervical sympathetic nerve become stimulated, causing contraction of the muscle fibres supplied by it, of which one set are those that dilate the pupil. Every anæsthetist knows that if an operation is commenced before a patient has become fully insensitive to pain, a skin incision will be followed by dilatation of the pupils. Claude Bernard,[10] in 1862, found that the experimental stimulation of the cerebral end of any sensory nerve was followed by dilatation of the pupils. Anderson describes how in a series of experiments he obtained such dilatation after the pupillo-constrictor tract had been divided, whereas he was unable to obtain it after the cervical sympathetic had been cut.

In the mydriasis brought about by emotional influences, acting through the sympathetic nerves on the dilator fibres of the iris, may be found an explanation of the influence which psychical conditions, such as those produced by worry and anxiety from bereavements or business losses, have in exciting the onset of glaucoma. Those of an emotional temperament manifest a predisposition to glaucoma, perhaps those who manage to suppress its outward signs more than those who give way to them. Females, the more emotional sex, suffer more frequently from glaucoma than males, especially the congestive type. Priestley Smith[11] estimated the ratio between the two sexes as 56·9 per cent. males against 43·1 per cent. females, and Kagoshima,[12] in Japan, as 61·9 per cent. females against 39·09 per cent. males. Widows seem specially liable to the disease. Thus I found out of the 117 cases 74 were females and 43 males; of the 74 females 38 were married, 27 widows, 7 single, 2 unrecorded; of the 43 males 31 were married, 8 widowers, 1 single, 3 unrecorded.

ANTAGONISM BETWEEN SPHINCTER AND DILATOR FIBRES.

Though in the reaction of the pupil to light in mammals the sphincter muscle is alone concerned, in respect to what is sometimes termed muscular tone some antagonism between the sphincter and dilator fibres appears to exist. In defective development, paralysis, and degeneration of the dilator fibres, the uncontrolled action of the sphincter muscle produces a condition of miosis. In Holth and Berner's[7] cases of congenital miosis they demonstrated defective development of the dilator muscle. In paralysis of the cervical sympathetic nerve-supply to the dilator muscle the pupil becomes contracted. The miosis met with in spinal disease, which though sometimes associated with loss of light reflex (Argyll Robertson pupil) may occur independently of it, is probably caused by a lesion of the cilio-spinal centre in the cord. Senile miosis is most likely due to degenerative changes in the dilator fibres, though of this at present there is no anatomical proof.

Congenital defects in the development of the sphincter muscle are only met with in association with gross deficiency in the formation of the iris. Apparently the sphincter muscle is not liable to senile degeneration as the dilator seems to be. When, however, it is paralysed with atropine the degree of mydriasis produced has been found to be decreased by section of the cervical sympathetic nerve, which seems to show that the unopposed antagonistic action of the dilator muscle produces a greater effect than that produced by mere paralysis of the sphincter. Contraction of the pupil has been frequently described as occurring in connexion with efforts to close the eye forcibly. It has been observed when the lids are kept apart by a speculum, whilst such efforts are being made. It has been suggested that this reflex is connected with the contraction of the orbicularis muscle, and that it is due to an overflow of stimulus passing from the nucleus of the seventh to that of the third. I would suggest that a more probable explanation is that the contraction of the pupil results from relaxation of the normal tone of the dilator muscle, associated with a relaxation of Müller's muscles, which raise the upper eyelid and protrude forwards the eyeball. When the eyelids are forcibly closed these two muscles, which, like the dilator fibres, are supplied by the cervical sympathetic nerve, would necessarily become relaxed.

The antagonistic action between sphincter and dilator muscles becomes strikingly manifest in diseased conditions, giving rise to the symptom which is termed hippus. A slight oscillation of the pupil after stimulation by light may sometimes be observed under normal conditions, but it becomes markedly increased when the conducting power for the afferent impulses of the light reaction are impeded, as in retrobulbar inflammation of the optic nerve.

CONSENSUAL REACTION IN RELATION TO BINOCULAR VISION.

Binocular vision, which is produced by the translation forwards of the eyes from the sides of the head so that the two fields of vision overlap, is present in some of the carnivorous fish, reptiles, and birds. In all these animals, however, there is complete decussation of the optic nerve fibres at the chiasma, so that the binocular vision is not stereoscopic vision, all the visual impressions received by the retina of one eye passing to the opposite side of the brain. All the afferent impulses for pupillary light reflex received from one eye likewise pass to the opposite side of the brain, and there is no consensual pupillary reaction. Amongst mammals there are some rodents who have complete decussation, and others, like rabbits, in whom it is almost complete. In the horse and calf, amongst the ungulata, it has been found that about one-sixth of the optic nerve fibres turn into the tract of the same vesicle at the pupillary margin, and run concentrically with the pupil in spaces in the stroma. When stimulated by light they expand antero-posteriorly, contracting laterally, so causing contraction of the pupil.

The formation of a screen in the front part of the eye with a central opening, capable of contraction and expansion, seems primarily to have been acquired for the purpose of regulating the amount of light admitted to the eye. In the eyes of cephalopods and fishes the static refraction is myopic and accommodation is for distance, produced by retraction of the globular lens into nearer approximation with the retina, without any alteration taking place in its curvature. These animals have no ciliary body and no suspensory ligament; the iris does not lie in contact with the lens and can play no part in accommodation.

Pupil Reaction in Fishes.

In fishes' eyes the muscles of the iris are but poorly developed, and the rapidity of reaction of their pupils to light is comparatively slow. In those of nocturnal habits, whose retinæ are probably particularly sensitive to light, the pupils in the daytime contract to an excessive minuteness (Beer). In some of the flat fish (as the thornback, *Raja clavata*) there is a projecting lobe from the upper border of the iris, which contracts over the pupil when the eye is exposed to bright sunshine. It consists of a crescent-shaped membrane with projecting processes at its free margin, and is composed of tissue similar to the stroma of the iris lined by pigment epithelium. In this animal, whose flat body-surfaces are truly dorsal and ventral, the eyes are situated dorsally and look directly upwards. It has no eyelids, and unless protected by some such pupillary curtain would be constantly exposed to the sun's glare. Flat fish, such as plaice (*Pleuronectes platessa*), in whom the body is flattened from side to side, not from above downwards, have their heads so twisted that both eyes are on the upper surface, but raised up from it so that their optical axes are directed laterally, and the pupils do not require protection by an extra lobe of the iris. In the eyes of many fish the membrane argentina of the choroid is continued on into the iris, where it forms a brilliantly reflecting surface, by which objects at the short range for which their eyes are focused when at rest can be illuminated. Possibly the sphincter muscle of the iris by its contraction to light may, in these animals, serve the subsidiary purpose of increasing the reflecting power of the membrane by making it tense.

The most remarkable form of adaptation in the eyes of fishes to suit different environments is that found in the *Anableps tetrophthalmus*, in which the cornea is divided into two halves by a dark strip of conjunctiva extending horizontally across it, and where the iris is perforated by two pupils, one opposite each division of the cornea. By this arrangement, and by the elevated position of the eyes on the surface of the animal's head, it is able to swim on the surface of the water, using the upper pupil and upper half of the cornea for aerial vision, and the lower pupil and lower half of the cornea for subaqueous vision. Though a different form of dioptric apparatus is necessary for vision in the two different media, for each a contractile pupil is required.

Contraction of Iris in Mammals a Reflex Act.

In the course of evolution the contractile power of the muscular tissue of the iris becomes changed, from one of direct action to the stimulus of light into a reflex act. No contraction of the iris tissue to light takes place in mammals when the iris tissue has been severed from its connexions with the central nervous system. It loses its phototactic action but retains its contractile power. In the reflex act of the pupil following the stimulation of the retina by light, the sphincter muscle, which is innervated by the third cranial nerve from fibres originating in its nucleus in the floor of the aqueduct of Sylvius, seems to be alone concerned. Several observers have found that after section of the third nerve variations in light produce no effect on the pupil. When the sphincter has been paralysed by the instillation of atropine no further dilation is effected by decreasing illumination. The dilator fibres of the iris, which are innervated by the cervical sympathetic, when they lose their phototactic powers, play, therefore, no part as an antagonistic to the sphincter in the pupillary-light regulating mechanism. Their action must have been evolved for some entirely different purpose.

EXPLANATION OF LONG COURSE OF FIBRES SUPPLYING DILATOR MUSCLE OF IRIS.

The nerve fibres supplying the dilator muscle of the iris take what at first seems to be a strangely long and circuitous course. Much experimental work has shown that, starting somewhere in the mesencephalon, they extend through the medulla oblongata into the lateral columns of the cord to the centrum cilio-spinale inferius in the dorsal region. They leave the cord by the ventral roots of the first, second, and third dorsal nerves to join the cervical sympathetic, from which they pass through the Gasserian ganglion to the first division of the fifth nerve and enter the eye with the long ciliary nerves. The excursion of these fibres down to the centrum cilio-spinale inferius in the dorsal cord seems to indicate that they were evolved at a time when, as in fish and amphibia, the cervical region was undeveloped, and that the displacement of the centre from the neighbourhood of the eye has been occasioned by the development of the neck.

On this matter I cannot do better than quote what Ferrier [8] has written:—

> The vasomotor nerves of the head and the dilator nerves of the pupil seem at first sight to pursue an unnecessarily roundabout path. Having their centres in the medulla oblongata, why, one asks, should they go all the way down to the upper dorsal region of the cord before emerging to join the sympathetics, seeing that anatomically they might reach their destination in a more direct manner? The explanation of this fact is without doubt to be sought for in embryology. I had, on purely physiological grounds, formed the speculation that the medulla oblongata should, as regards all organic functions, be looked upon as the direct continuation of the dorsal spinal cord, the cervical region being merely intercalated for the innervation of the upper extremities and their related parts. My friend Prof. Kitchen Parker, to whom I referred on this point, kindly pointed out to me facts of development which seem to me entirely in harmony with the speculation I had formed. Thus in the embryo of all animals, the heart is at first in close relation with the head and the cerebral vesicles, but ultimately, as development proceeds, comes to lie at some distance posteriorly. The distance is extremely variable in different classes of animals, and depends on the number of cervical segments which are developed. In osseous fishes, in which the cervical region is absent, the heart is in the closest relation with the head, and the first spinal nerve, succeeding the vagus, communicates with the second, and supplies among others the muscles of the pectoral fin, which is the homologue of the hand or arm in man. Therefore the region of the spinal cord, which, as regards function at least, corresponds to the lower cervical or upper dorsal segments in the monkey, comes in the fish immediately after the origin of the vagus. In the myxine, or hag, however, the heart is situated a very considerable distance posterior to the head—below the fortieth spinal segment. This has been conditioned by the development of a large number of segments for the powerful musculature of the upper part of the body. There is every reason for believing, however, that in the embryo hag the heart at first occupies the same position in relation to the head that it does in other embryos. As, therefore, the vagus elongates in proportion to the distance of the heart and viscera from the medulla oblongata, so also the spinal tracts which connect the face, originally short and direct, become elongated by the intercalation of the cervical segments which are developed for the innervation of the upper extremities and their annexes. Hence they ultimately emerge by the anterior roots of the upper dorsal nerves, and re-ascend in the cervical sympathetic to their destination.

DILATATION OF PUPIL FROM EMOTIONAL AND SENSORY STIMULI.

Dilatation of the pupil occurs not only from absence of light, but also as the result of the application of sensory stimuli to various parts of the body, and of physical influences. Experimentally it may be produced by the stimulation of the cerebral end of any sensory nerve, and by the stimulation of certain areas on the cerebral cortex. Parsons[9] found that electrical stimulation of the cortex of cats, dogs, and monkeys, in the neighbourhood of the crucial sulcus and over a considerable area of the occipital region, produced wide dilatation of the pupils when the cervical sympathetic nerves were intact, and a dilatation of about a half or two-thirds that amount when those nerves had been divided.

Dilatation of the pupil caused by section of the third nerve may be increased by stimulation of the cervical sympathetic; and cocaine, which acts by stimulation of the terminals of the cervical sympathetic, will cause a pupil dilated by atropine to enlarge still further. Fright, such as that produced by a sudden and unexpected noise, causes the pupils to dilate widely, even whilst the retina is being stimulated by exposure to bright light. Wide dilatation of the pupil enlarges the field of vision by allowing rays of light to pass into the eye which, owing to their obliquity, would otherwise be cut off. Such an enlargement of the field of vision is of considerable importance to those animals which require a large range of circumferential vision to warn them of the approach of danger. In most of the ungulata, whose safety mainly depends on their rapidity of flight, an increased range of circumferential vision is further provided for by horizontally oval-shaped pupils.

Stimulation of the cervical sympathetic nerve, besides exciting into action the dilator muscle fibres of the iris, causes contraction of the two sets of unstriated muscle fibres in the orbit described by Müller—viz., that which causes widening of the palpebral fissure by retraction of the upper eyelid, and that which causes protrusion of the eyeball. An enlargement of the palpebral fissure and an increased prominence of the eyeball, like dilatation of the pupil, serve to increase the range of vision: the three symptoms are characteristic of fright. It seems, therefore, most probable that they have all three been evolved for the same purpose—that is, to enable animals to perceive and escape quickly from approaching foes.

The instinct of flight, which is usually evoked by the emotion of fear, may be called into action in different ways. The stimulus may be received through the auditory nerve from some sudden and unexpected sound; through the optic nerve by the perception of some approaching danger; or through the cutaneous surface by the sensation of pain. In whichever way elicited the fibres of the cervical sympathetic nerve become stimulated, causing contraction of the muscle fibres supplied by it, of which one set are those that dilate the pupil. Every anæsthetist knows that if an operation is commenced before a patient has become fully insensitive to pain, a skin incision will be followed by dilatation of the pupils. Claude Bernard,[10] in 1862, found that the experimental stimulation of the cerebral end of any sensory nerve was followed by dilatation of the pupils. Anderson describes how in a series of experiments he obtained such dilatation after the pupillo-constrictor tract had been divided, whereas he was unable to obtain it after the cervical sympathetic had been cut.

In the mydriasis brought about by emotional influences, acting through the sympathetic nerves on the dilator fibres of the iris, may be found an explanation of the influence which psychical conditions, such as those produced by worry and anxiety from bereavements or business losses, have in exciting the onset of glaucoma. Those of an emotional temperament manifest a predisposition to glaucoma, perhaps those who manage to suppress its outward signs more than those who give way to them. Females, the more emotional sex, suffer more frequently from glaucoma than males, especially the congestive type. Priestley Smith[11] estimated the ratio between the two sexes as 56·9 per cent. males against 43·1 per cent. females, and Kagoshima,[12] in Japan, as 61·9 per cent. females against 39·09 per cent. males. Widows seem specially liable to the disease. Thus I found out of the 117 cases 74 were females and 43 males; of the 74 females 38 were married, 27 widows, 7 single, 2 unrecorded; of the 43 males 31 were married, 8 widowers, 1 single, 3 unrecorded.

ANTAGONISM BETWEEN SPHINCTER AND DILATOR FIBRES.

Though in the reaction of the pupil to light in mammals the sphincter muscle is alone concerned, in respect to what is sometimes termed muscular tone some antagonism between the sphincter and dilator fibres appears to exist. In defective development, paralysis, and degeneration of the dilator fibres, the uncontrolled action of the sphincter muscle produces a condition of miosis. In Holth and Berner's[7] cases of congenital miosis they demonstrated defective development of the dilator muscle. In paralysis of the cervical sympathetic nerve-supply to the dilator muscle the pupil becomes contracted. The miosis met with in spinal disease, which though sometimes associated with loss of light reflex (Argyll Robertson pupil) may occur independently of it, is probably caused by a lesion of the cilio-spinal centre in the cord. Senile miosis is most likely due to degenerative changes in the dilator fibres, though of this at present there is no anatomical proof.

Congenital defects in the development of the sphincter muscle are only met with in association with gross deficiency in the formation of the iris. Apparently the sphincter muscle is not liable to senile degeneration as the dilator seems to be. When, however, it is paralysed with atropine the degree of mydriasis produced has been found to be decreased by section of the cervical sympathetic nerve, which seems to show that the unopposed antagonistic action of the dilator muscle produces a greater effect than that produced by mere paralysis of the sphincter. Contraction of the pupil has been frequently described as occurring in connexion with efforts to close the eye forcibly. It has been suggested that this reflex is connected with the contraction of the orbicularis muscle, and that it is due to an overflow of stimulus passing from the nucleus of the seventh to that of the third. I would suggest that a more probable explanation is that the contraction of the pupil results from relaxation of the normal tone of the dilator muscle, associated with a relaxation of Müller's muscles, which raise the upper eyelid and protrude forwards the eyeball. When the eyelids are forcibly closed these two muscles, which, like the dilator fibres, are supplied by the cervical sympathetic nerve, would necessarily become relaxed.

The antagonistic action between sphincter and dilator muscles becomes strikingly manifest in diseased conditions, giving rise to the symptom which is termed hippus. A slight oscillation of the pupil after stimulation by light may sometimes be observed under normal conditions, but it becomes markedly increased when the conducting power for the afferent impulses of the light reaction are impeded, as in retrobulbar inflammation of the optic nerve.

CONSENSUAL REACTION IN RELATION TO BINOCULAR VISION.

Binocular vision, which is produced by the translation forwards of the eyes from the sides of the head so that the two fields of vision overlap, is present in some of the carnivorous fish, reptiles, and birds. In all these animals, however, there is complete decussation of the optic nerve fibres at the chiasma, so that the binocular vision is not stereoscopic vision, all the visual impressions received by the retina of one eye passing to the opposite side of the brain. All the afferent impulses for pupillary light reflex received from one eye likewise pass to the opposite side of the brain, and there is no consensual pupillary reaction. Amongst mammals there are some rodents who have complete decussation, and others, like rabbits, in whom it is almost complete. In the horse and calf, amongst the ungulata, it has been found that about one-sixth of the optic nerve fibres turn into the tract of the same side. Neither in rodents nor in the ungulata is any consensual pupillary reaction to be detected; apparently in those of them in which semi-decussation takes place there is an absence of pupillary fibres in the uncrossed bundles. It is in the carnivorous mammals, to whom stereoscopic binocular vision is of some importance for the judgment of distances in pouncing on their prey, that consensual pupillary light reflex is first met with.

Wilfred Harris [13] found that experimental division of the optic tract on one side in cats produced distinct homonymous hemianopia, with the hemianopic pupil reaction, and with considerable diminution of the pupil reaction to direct light in the opposite eye, though its consensual reaction was brisk on exposure of the other eye to light. This indicates, as Wilfred Harris points out, that the decussating optic bundle is much larger than the uncrossed bundle in the cat, as Ramón y Cajal has figured, and therefore the light stimulus, when conducted only by the small uncrossed bundle from the opposite eye, is much more feeble in causing pupil contraction, than when it is conducted by the large decussating bundle from the nasal side of the retina on the same side. In man, in cases where one optic tract is affected by disease, and where there is hemianopic pupil reaction, the briskness of the two pupils to light is nearly equal, whichever pupil is exposed to light. From which, as Harris says, we may infer that the size of the uncrossed bundle in man, and probably also in monkeys, is proportionally larger than in cats.

The highest form of stereoscopic binocular vision is that in which impressions from each macula become super-imposed on each side of the brain. The fovea centralis is only met with in mammals amongst apes and man. It has been developed as the result of arboreal life in which the fore limbs are used for prehensile purposes, and for picking up and conveying food to the mouth. With the development of acute central stereoscopic vision there has arisen the capacity of accommodation and convergence, and associated contraction of the pupil.

Reaction of Pupils in Association with Accommodation and Convergence.

The lowest mammals have little if any power of accommodation. In the echidna and in the great ant-eater the ciliary muscle is practically non-existent. In rabbits only a few scanty fibres are recognisable. In the ungulata longitudinal fibres form a considerable band, which becomes more pronounced in the carnivora. The aquatic carnivora, such as seals and otters, require to see in two different environments, air and water. The similarity of the refractive index of the cornea and water tends to render them, when in that media, highly hypermetropic, to overcome which they have developed considerably their intra-ocular muscles, so increasing their powers of accommodation. The sphincter muscle of the iris in these animals is unusually large, extending even up to its periphery. In apes and man amongst mammals the power of accommodation and the ciliary muscle reach their greatest development.

In mammals which have their eyes situated laterally in the head, as in most of the rodents, no convergence can take place. In the ungulata, when their attention is suddenly attracted, some movement from divergence toward parallelism can be detected. In the carnivora more obvious attempts at convergence take place. It is, however, only when we come to the monkeys which have developed a fovea with a high degree of central acuity of vision, that the power of converging the optical axes becomes a prominent feature. Contraction of the pupils, by cutting off circles of diffusion, must assist those animals whose eyes in the static condition are focused for distance, in seeing near objects apart from any accommodation which may take place. In a paper entitled "Apparent Accommodation in Aphakia," which I read at the Ophthalmological Society in 1915, I showed that after the removal of soft cataracts the presence of a small central hole in the capsule, together with a freely acting pupil, enables a patient to obtain full acuity of central vision both for far and near with the same lens. For animals requiring acute central stereoscopic vision for different distances the power of varying the size of the pupils in association with accommodation and convergence must be of great assistance. It is a form of pupillary reaction which has been evolved much later than, and quite independently of, the pupillary light reflex. The light reaction is a simple reflex act in which the centres in the mesencephalon are alone involved. The reaction of the pupils in association with convergence is not a simple reflex act, but an involuntary act which has become linked up with a voluntary one represented by centres in the visual cortex.

Contraction of the pupils in association with convergence without accommodation has been definitely demonstrated, but it is very doubtful if contraction takes place in association with accommodation apart from convergence. All three movements are connected with different parts of the third nerve nucleus; the impulses stimulating both the ciliary muscle and the sphincter muscle of the iris pass through the ciliary ganglion and enter the eyeball along the short ciliary nerves. It is probable that accommodation and contraction of the pupil, though not themselves definitely connected, both bear the same relation to convergence, and are both together stimulated into action by that voluntary movement under the control of higher centres in the cerebral cortex.

The independence of the pupillary reactions in connexion with light and convergence, both as regards their evolution and control, is of considerable interest in connexion with diseased conditions where one mode of reaction may be destroyed whilst the other remains unimpaired. In the Argyll Robertson phenomenon, where the reaction to light is lost whilst that to convergence remains, and which is such a common accompaniment of tabes, the lesion is probably one affecting the centripetal pupillary light reflex fibres somewhere between the optic tract and the oculo-motor nucleus, though as yet its site has not definitely been demonstrated by anatomical investigation.

The opposite condition, that of loss of pupillary reaction in association with convergence whilst that in connexion with light remains, is of much less frequent occurrence. It has been met with as a congenital defect, in rare cases in connexion with tabes, in cases of syphilitic basal meningitis and tumours of the corpora quadrigemina. A few cases of paresis of convergence without loss of conjugate movements in any direction have been recorded. Thus Henry Eales,[14] in 1884, described the case of a girl, aged 13, in whom, without any other sign of disease, there was complete paralysis of convergence and accommodation, the bilateral conjugate movements, both upwards and downwards and from side to side, being unimpaired. Though both pupils acted freely to light they did not contract when she looked at near objects.

The close association of the action of the pupils with convergence is also well demonstrated by a case recorded by Holmes Spicer [15] in 1002. It was that of a man, aged 44, who 15 years previously had primary syphilis and presented symptoms of early tabes. His pupils did not react to light and his convergence was weak. When he looked steadily at a near object his visual axes were parallel and the pupils small and equal to 2 mm. If one eye was covered it diverged and at the same time the pupil of the fixing eye as well as of the covered eye slowly dilated to 8 mm. On bringing both eyes into action again the visual axes became parallel and the pupils contracted. His convergence being weak to maintain binocular vision for distance, a strong effort at convergence was necessary; the association of the action of the pupils with convergence caused a marked contraction of the pupils. When one eye was covered it diverged, relaxation of convergence took place, and at the same time the pupils dilated.

EVOLUTION OF INTRA-OCULAR MUSCLES.

It is generally agreed that mammals in the process of evolution branched off at an early date, as a different stem from reptiles and birds, from some common reptile root. The sauropsids (under which term reptiles and birds are classed) and mammals each present anatomical characteristics which, whilst common to all their members, are markedly different in the two groups. This applies to the structure of their intra-ocular muscles; in the sauropsids they are composed of striped fibres and in mammals of unstriped. The first discovery of an internal muscular apparatus in the ciliary region was made in birds in 1813 by Dr. Crampton, afterwards Sir Philip Crampton, Bart., who was three times President of the Royal College of Surgeons in Ireland. Though earlier writers had put forward theories of accommodation which involved the presence of muscular fibres none had previously demonstrated their existence by dissection.

Reptiles, such as lizards who feed on small insects which they snap up rapidly with their tongues, require not only a very high degree of acuity of vision, but also the power of accommodating up to within a few centimetres. The chameleon which has remarkable powers of rotating its two eyes in different directions, can converge their axes on the victim it is about to catch and devour. The rapacious birds which sight their prey from enormous distances, and those of the sparrow kind which feed on minute seeds and insects, possess not only a visual acuity but also a power of accommodation vastly superior to that of man. It is not surprising, therefore, to find that the iris, which plays such an important part in association with accommodation, is provided with more extensive and more rapidly active muscular tissue in reptiles and birds than in mammals.

The general plan of the arrangement of the striate muscle fibres in birds and reptiles is in two planes: the anterior sphincter fibres running a circular course, and the posterior dilator fibres having a radial direction. In birds there is a marked development of the circular fibres at the periphery of the iris where they form a distinct prominence on its surface. Variations from this general plan are met with in different species. The striated sphincter pupillæ muscle in birds has, like the unstriated sphincter in mammals, been shown by Nussbaum to be formed from epithelial cells at the pupillary margin of the optic cup. Lewis has further shown that the more peripheral muscle fibres in bird's irides are produced from cells budding off the anterior pigment epithelial layer some distance external to the pupillary margin. Crampton's muscle in birds, Lewis[16] found, like the ciliary muscle in mammals, to be derived from mesoblast. As the optic nerve fibres decussate completely at the chiasma in birds and reptiles, they have no consensual reaction of the pupils to light and no stereoscopic vision, as in man. Birds, however, possess some voluntary control over the movements of their pupils, this voluntary movement being bilateral whilst the light reflex is only unilateral.

EVOLUTION OF NUCLEUS OF THE THIRD NERVE.

The researches of Davidson Black[17] and others on the phenomenon of Kappers's[18] neurobiotaxis (i.e., the shifting of nerve cells in the central nerve system in the direction of the point whence the majority of stimuli reach them) have shown that in the phylogenetic development of the third nerve nucleus certain changes take place which may be correlated with elaboration in the intra- and extra-ocular movements. Anatomically the third nerve nucleus in man and monkeys is found to be composed of different groups of cells. There are two main lateral ones composed of large cells, crescentic in shape with the concavity outwards; and a median one, known as the nucleus of Perlia, also composed of large cells. Between the anterior rounded extremities of the lateral crescentic nuclei, almost touching the middle line, are two groups of smaller cells which are termed the Edinger-Westphal nuclei.

The most recent experimental work on the association of different parts of this nucleus with the control of the intra-ocular muscles tends to prove that the Edinger-Westphal groups of cells are centres for constriction of the pupil, that the centre for convergence being situated on the inner aspect of the central part of the median group of cells, and that for accommodation at its posterior end. In the lowest species of fish and in sharks the nucleus of the third nerve is found to consist of a group of cells undifferentiated into any specific areas. Some differentiation away from this primitive condition is met with in ganoid and teleostean fish, but not in the dipnoans or lung fish, which latter present the most distinct signs of transition between fish and amphibians. Such differentiation can, therefore, hardly be regarded as a precursor of the subgrouping which has been found in anuran amphibia, reptiles, birds, and mammals. Writing on this matter Davidson Black says:

> It would thus seem probable that the factors which determined the anuran oculomotor cell-arrangement must have appeared comparatively late in phylogeny. The eyes of most fishes are normally focused for near objects when at rest, and since the eyes of most amphibians, reptiles, birds, and mammals are normally focused for distance, it is not improbable that the chief original cause of the amphibian oculomotor specialisation may be seen in the readjustment of accommodation which must have taken place in phylogeny during the evolution of the amphibian type.

Kappers pointed out how, in the arrangements of the elements of the anuran amphibian oculomotor nucleus, a first stage in the evolution of the more highly specialised sauropsidan condition may be recognised. More recently the evolution of the Edinger-Westphal nuclei, the blending in a central raphé of the nuclei of the internal recti, with the growth of the nucleus of Perlia, in association with the development of accommodation and convergence, has been depicted in a graphic fashion by Brouwer.

CENTRES FOR CONVERGENCE AND DIVERGENCE.

In spite of the large amount of experimental work that has been done in connexion with the associated movements of the eyes, there is still much to be learnt regarding the cortical centres for convergence and divergence, and as to the course taken by the fibres which connect them with nuclei of the ocular nerves in the aqueduct of Sylvius. Such evidence as we have seems to show that in the cerebral cortex there are centres both in the occipital and frontal lobes, the bilateral stimulation of which gives rise to these associated movements of the eyes. In the occipital lobes the centres for ocular movement are situated in close proximity to the visual centres, and seem closely associated with sensory stimuli, the movements being made for the purpose of fusing images received from the two eyes in the desire for binocular vision. In the frontal lobe the centre for convergence has been located near the angle of the precentral fissure (Sherrington), and that for divergence in front of the middle of that fissure (Bechterew); they seem to be more particularly connected with voluntary movements.

As the result of a consideration of his own and others' experiments, of the effects on the pupil from stimulation of various areas in the cerebral cortex, Parsons[9] says it seems probable that there are foci for pupil constriction both in the frontal and occipital areas, but that they are often masked by the dilator effects, which are much more readily produced. He sums up his observations by saying:—

> It is unlikely that we are dealing with "centres" for the pupils, in the ordinary sense of the term. We have found that the effect is most specifically obtained from the areas which are concerned with ocular movements, whether from the motor or the sensory side. Moreover, it would seem that the effect is indissolubly connected with those movements, and does not occur in their absence. Hence it is most reasonable to conclude that the phenomenon is an associated effect.

In such experiments I would suggest that it is most probable that the centres for convergence or divergence, being either excited or inhibited, the associated movement of either contraction or dilatation of the pupil is produced.

Summary.

1. The muscle fibres of the iris are developed from cells of the outer layer of the secondary optic vesicle, cells which in the hinder part of the eye are known to possess a capacity for movement in the direction of light.

2. In some of the cold-blooded vertebrata the muscles of the iris have been found to react directly to the stimulus of light, apart from any nervous impulse.

3. In the warm-blooded vertebrata the direct phototactic action of the iris is lost, and becomes replaced by a more quickly acting reaction due to nervous mechanism, the afferent impulse for which is received through the retina and optic nerve.

4. That the dilator fibres of the iris in warm-blooded animals are not concerned in the reflex light-regulating mechanism, and that their action must have been evolved for a different purpose.

5. That these dilator fibres are supplied by the cervical sympathetic nerve which also supplies unstriated muscle fibres in the eyelid and orbit, muscles which become excited into action in connexion with the emotion of fear.

6. Enlargement of the pupils, increased prominence of the eyeballs, and widening of the palpebral fissure increase the range of circumferential vision, thereby assisting an animal in perceiving the early approach of danger and in obtaining safety in flight.

7. Consensual reaction of the pupils to light is of assistance in stereoscopic binocular vision, in which impressions received from the retinæ of the two eyes become superimposed on the same side of the brain. It is only met with in the higher mammals, in which semi-decussation takes place at the optic chiasma.

8. The reaction of the pupils in association with accommodation and convergence has been evolved much later, and quite independently, of their reaction to light. In it the two involuntary acts of contraction of the sphincter of the iris and of the ciliary muscle become associated with the voluntary one of convergence, which is represented by centres in the visual cortex.

9. Convergence can only take place in mammals where the eyes are situated in the front of the head, and where the optic axes are parallel in direction. It only becomes a pronounced feature in man and monkeys in whom a high degree of central acuity of vision has been acquired.

10. Correlated with the increasing diversity of actions of the sphincter muscle of the iris there is an increased functional specificity of the cells of the third nerve nucleus.

ON THE RELATION BETWEEN GENERAL PARALYSIS AND SOMATIC SYPHILIS.*

By PHŒBE M. BIGLAND, M.D., Ch.B. Liverp., M.R.C.P. Lond.,
HON. ASSISTANT PHYSICIAN, LIVERPOOL CHEST HOSPITAL; LECTURER IN PATHOLOGY, UNIVERSITY OF LIVERPOOL;

GEORGE A. WATSON, M.B., C.M. Edin.,
PATHOLOGIST, LANCASHIRE COUNTY MENTAL HOSPITALS, RAINHILL AND WINWICK;

AND

A. DOUGLAS BIGLAND, M.A. Camb., M.D., Ch.B. Liverp., M.R.C.P. Lond.,
HON. ASSISTANT PHYSICIAN, LIVERPOOL ROYAL INFIRMARY: HON. CONSULTING PHYSICIAN, LANCASHIRE COUNTY MENTAL HOSPITAL, RAINHILL.

What is it that in a relatively small number of cases causes the *Spironema pallidum* to invade the nervous system? To obtain an answer to this question is the object of our work.

Two possibilities present themselves: First, that the controlling factor lies in the organism itself or, in other words, that a neurotropic strain of spirochæte exists; secondly, that tissue predilection is the deciding factor, and that the nervous system is infected because it offers less resistance to the invading organism. It is well known that the tissues of certain individuals wear out more easily than do those of others. A nervous system having what is termed by Bolton[1] this "defective durability," is liable, when invaded by an organism such as the spirochæte, to fall a prey to it.

Our original question is not a mere academic one, and the correct answer will prove of immense importance in practical medicine. For this reason the research is of general interest. General paralysis is chosen as our type of neuro-syphilis because the diagnosis by modern serological methods is certain and can be confirmed by exactly determined post-mortem findings; also because it is the only disease of this nature concerning which adequate pathological details in sufficient number could be collected.

Neuro-syphilis may be divided into two varieties: (1) The meningo-vascular type, where the supporting structures are primarily affected and the nervous tissue only secondarily. Examples are gumma and gummatous meningitis at one end of the scale, and purely vascular lesions, such as cerebral softening and so-called myelitis, at the other. Between these two lie the intermediate forms which may be classed generally as disseminated cerebro-spinal syphilis. It is contended by us that this meningo-vascular type is not in the anatomical sense *neuro*-syphilis at all, but rather merely a syphilitic invasion of those nutrient and supporting structures which are necessary for the functioning of the nervous system. (2) The variety in which the attack falls upon the nervous tissue proper, so-called parenchymatous neuro-syphilis, of which general paralysis and tabes are the only representatives.

If there be a special neurotropic variety of spirochæte responsible for general paralysis either it should attack the nervous system only, or, if it does attack the somatic system, then the findings here should be slight, or at any rate different from those found in non-nervous syphilis.

A study of the Wassermann reaction in cases of general paralysis led us to assume at the outset that somatic lesions would be found, for in all the samples of blood in these cases examined by us without exception a strongly positive reaction was obtained. If this means that the body tissues contain living spirochætes or their products, then the matter resolves itself into a search for these lesions, knowing that they must be present.

---

* A paper read before the Liverpool Medical Institution.

Analysis of Post-mortem Records of General Paralysis.

The first part of the research consists of the analysis of the records of post-mortem examinations upon cases of general paralysis made by one of us (G. A. W.) at the Lancashire County Mental Hospital, Rainhill. Out of a total of 2622 autopsy records there were 529 cases of general paralysis; 1485 of the 2622 autopsies were upon male and 1137 upon female cases. The 1485 male cases provided 429 examples of general paralysis, a percentage of 28·9; the 1137 female cases provided 110 examples, a percentage of 9·6 total female autopsies. This last figure is striking, showing as it does that the disease in this institution is only about three times more common in men than in women; this is a very much lower ratio than that usually given. In addition to these cases there were records of two male and nine female juvenile paralytics.

For the purposes of this research in order to maintain a uniform standard only those records made by one of us (G. A. W.) were used—viz., 424 male and 105 female cases. In a few it had only been possible, for various reasons, to make a partial examination, but in all the skull and brain had been examined. All the cases had been proved by examination of the brain to be undoubted cases of general paralysis, and in several the spirochæte had been demonstrated in the brain substance. No reference is made here to the pathological findings with regard to the brain and nervous tissue, as the object of our work was to discover, by examination of cases known to be general paralysis, any evidence for or against the theory that a special variety of spirochæte is responsible for neuro-syphilis.

As post-mortem findings vary with the age of the subject, we first analysed the cases with regard to the age at death. (Table I.)

TABLE I.—*Age Incidence at Death.*

Age period.	Males.	Females.	Age period.	Males.	Females.
20–25	4	0	51–55	40	11
26–30	21	5	56–60	28	5
31–35	67	11	61–65	6	1
36–40	101	26	66–70	5	0
41–45	81	27	70–75	1	0
46–50	72	19	Age unknown.	2	—

The average age at death of 426 males was 42·6 years, while that of 105 females was 42·4 years. These figures show that the largest number of males die between the ages of 36 and 40 years, the figure for this period being considerably higher than that for the age period 41–45, whereas in women the percentage death-rate for these two periods is practically the same. The average age at death, however, shows remarkable agreement.

Next our attention was directed to the records dealing with evidences of syphilitic infection on the external surface of the body with the following results:—

(*a*) Well-defined scars of the primary sore were found in 81 of the male cases, indefinite scars in a further 23, and inguinal scars in a further 6 cases, making a total of 110, a percentage of 26. This figure, so far as our observations go, is considerably higher than that found in the venereal department records, and it is particularly interesting in view of the oft-repeated statement that general paralysis frequently occurs in those individuals who never knew that they had been infected with syphilis.

(*b*) Pigmented scars on the legs were found in 36 male cases, and in only three of the females.

(*c*) Another extraordinary finding, which has no direct bearing on the present question, but which is of sufficient interest to warrant its mention, is the incidence of elaborate tattooing in these cases. Of the 424 male paralytics 102 were thus adorned, a percentage of 24, whereas the percentage of cases showing tattooing among 899 other male lunatics was only 6·2. Of the 105 women paralytics the incidence of tattooing was 5·9 per cent., while in 1032 other female lunatics only four showed this (0·38 per cent.). The tattoo marks in the female non-paralytics were simple initials only, and among the males those found in the non-syphilitic cases tended to be of a much simpler type.

Statistics concerning the condition of the skull revealed an increase in density in the large majority of the cases examined. The typical paretic skull is much thicker and harder than normal, with a disappearance of the diploë and its replacement by solid bone. Well-defined symmetrical bossing of the frontal bones was noted in a few instances, while a roughening or corrugation of the inner table of the frontal bone, together with a deepening of the groove for the middle meningeal artery, were fairly typical findings. Much rarer were irregular areas of cranial thinning. (Table II.)

TABLE II.—*Statistics as to the Condition of the Skull.*

Condition.	Male.	Female.
Normal	45	10
Density increased	59	17
Density much increased	174	44
Density very much increased ..	124	28
Density extremely increased ..	12	5
Bosses	11	6
Paget's disease	0	1

Most important changes were found in the cardiovascular system. The aorta in all but seven cases showed some pathological change, the condition found in 392 instances being syphilitic aortitis, apparently exactly similar to that met with in somatic syphilis. This aortitis is characterised by the presence of comparatively large raised areas of pearly-white fibrosis, in which later contraction takes place, resulting in very typical radiating scars. The pearly nodules contain no fat, they do not ulcerate, and no lime salts are deposited in them. The patches occur first and are usually most marked in the first part of the thoracic aorta, in this way differing from ordinary atheroma which begins, and is most marked, in the descending part of the thoracic and in the abdominal aorta. The pearly-white patches occur in quite young persons; in our series they were found in all of the 18 cases between 21 and 30 years of age. In the older subjects it is common to find ordinary atheroma with ulceration and calcification associated with the syphilitic condition. This is due to the other causes of arterial degeneration coming into action. We have, therefore, tabulated (Table III.) the aortic condition into three classes: (1) Pearly patches only; (2) pearly patches with ordinary atheroma; (3) ordinary

TABLE III.—*Showing the Condition of the Aorta in G.P.I. at the Different Age Periods.*

Age period.	Aorta normal.	Extent.	Pathological change.		
			Pearly patches.	Pearly patches & atheroma.	Atheroma only.

atheroma only. As there were no essential differences in men as opposed to women in this series the figures have been added together. It is extraordinary that there were only seven normal aortas in the whole series, and of these four were in men between the ages of 41 and 50.

We were struck by the unexpected finding that the incidence of aneurysm is rare. Though slight dilatation of the aorta is fairly common, being found in 30 of our cases, there were only two saccular aneurysms and one of the fusiform variety. Of the saccular aneurysms one was in a woman who died from its rupture. It is remarkable that though the first part of the aorta is affected in these cases the heart valves usually escape. In this series the valves, usually the mitral, were thickened in 22 cases, and showed ordinary atheroma in nine cases only. One of us (G. A. W.) has demonstrated spirochætes in the aortic lesions in cases of general paralysis. Another remarkable fact is that true endarteritis obliterans is rarely found in the cerebral arteries in these cases, the common change being a thickening or wiry condition of the smaller arteries. We have analysed the condition found in our series into three classes: (1) Those showing increased density of the smaller arteries; (2) those showing a fibrous nodular condition; and (3) those showing ordinary arterio-sclerosis only. Thirty-two males and thirteen females only had normal cerebral arteries. (Table IV.)

TABLE IV.—*Showing Condition of the Cerebral Arteries in G.P.I.*

1. Increased density of smaller arteries.		
Some increase	159 males,	31 females.
Marked increase	113 „	28 „
Very marked increase ..	45 „	13 „
2. Arteries show fibrous nodules.		
Present	39 males,	4 females.
Marked	25 „	5 „
Very marked	5 „	3 „
3. Arteries show ordinary arterio-sclerosis.		
Present	16 males,	3 females.
Marked	11 „	3 „
Very marked	9 „	2 „
Extremely marked ..	1 male,	0 „
Arteries normal	18 males,	13 „

Examination of the internal organs revealed certain pathological conditions. The spleen, kidneys, suprarenals, and liver showed an increase in the amount of fibrous tissue present. This increase takes the form of a diffuse fibrosis, so that the organ feels harder and heavier than normal. This change is most marked in the spleen, less so in the kidneys, and least of all in the liver. The typical changes in the kidneys will not be confused with ordinary cirrhosis, for it occurs in much younger persons, its distribution is different, and it is not associated with the presence of small cysts. It is peculiar that in the livers examined no scarring, such as is so common in syphilitic cases in general hospitals, was noted. In many of the cases, especially those which had an associated tuberculosis, the liver was fatty; in spite of this an increased fibrosis was obvious in many of them. Marked fibrosis is common in the testicle, but we have no exact figures as to the numbers.

Details of Fibrosis of the Solid Organs.

The degree of fibrosis was divided into four groups—viz., slight increase (+), distinct increase (+ +), great increase (+ + +), very great increase (+ + + +). (Table V.)

Though it may be regarded as a pathological axiom that syphilis produces fibrosis, yet it is common knowledge that with advancing age the density of the tissues may increase from various causes. In order to determine whether the age at death had any relationship to the density of the fibrosis, we have tabulated (Table VI.) the various degrees of fibrosis in the different age-periods.

TABLE V.

Organ.		No. examined.	Normal.	Degree of increase of density.					Other conditions.
				+	+ +	+ + +	+ + + +	Total	
Spleen	(M.)	316	1	15	80	185	30	310	5
	(F.)	83	0	7	28	41	4	80	3
Kidneys	(M.)	316	3	6	52	160	78	296	17
	(F.)	83	2	8	17	40	11	76	5
Liver	(M.)	316	3	46	104	123	18	291	22
	(F.)	83	2	12	30	14	3	59	22

M. = Males. F. = Females.

TABLE VI.—*Density of Fibrosis of Solid Organs at Different Age-Periods (Males).*

Organ.	Age-period.	Fibrosis. No. of cases.	Amount of fibrosis.			
			+	+ +	+ + +	+ + + +
Spleen ..	–20	1	0	0	1	0
	21–30	18	0	4	13	1
	31–40	117	4	30	66	17
	41–50	110	5	30	68	7
	51–60	53	3	12	34	4
	61–70	10	2	4	3	1
	Over 70	1	1	0	0	0
Kidneys ..	–20	1	0	0	1	0

	51–60	51	3	10	28	10
	61–70	9	2	2	5	0
	Over 70	0	0	0	0	0
Liver.. ..	–20	1	0	1	0	0
	21–30	18	1	4	12	1
	31–40	109	12	39	51	7
	41–50	105	21	36	43	5
	51–60	49	10	21	14	4
	61–70	8	2	2	3	1
	Over 70	1	0	1	0	0

A perusal of Table VI. clearly shows that the age of the patient has no relation to the amount of fibrosis present—for example, 72·2 per cent. of the cases between 21 and 30 years of age had a + + + fibrosis of the spleen, and 64 per cent. of those between 51 and 60. While in the case of the kidneys 61·1 per cent. between 21 and 30, and 54·9 per cent. between 51 and 60 had a + + + fibrosis. This is in accordance with the findings of other observers who have described marked fibrosis in early cases of general paralysis dying from some intercurrent disease. These results also go to disprove the theory that the fibrosis is not due to the syphilis, but to the associated septic conditions which frequently occur at the termination of long-standing illness. Other syphilitic lesions found were—four instances of gummata of the testes, kidney, spinal ganglion, and brain, the last being in a woman; three cases (two men and one woman) of syphilitic meningitis, and one female case of syphilitic osteitis. Interstitial keratitis was fairly common.

With regard to the presence of associated pathological conditions, it is interesting to note the relative frequency of tuberculosis. Ninety-seven (30 per cent.) of 324 complete male, and 32 (38·5 per cent.) of 83 complete female autopsies showed evidence of this disease. (Table VII.)

TABLE VII.—*Tuberculous Lesions in Cases of G.P.I.*

	Males.		Females.
Active T.B. of the lungs ..	20	......	19
Old T.B. of the lungs	75	......	13
T.B. ulceration of the intestines	8	......	6
T.B. Fallopian tubes	—	......	6
T.B. pancreas	1	......	0
Acute pneumonic phthisis	1	......	0

Eighty-four of the cases died of pneumonia, and in 14 of these gangrene of the lung had supervened. This percentage of gangrene appears to be much higher than that found in ordinary general hospital practice. Concerning the other organs, little remains to be said, but one further fact is worthy of note. As compared with the genital scars in the males and the evidence they provide of old venereal infection, a study of the Fallopian tubes in women paralytics is of interest. Of the 83 complete female post-mortem examinations, 57 showed old tubal adhesions, a percentage of 68·7; a few of these were undoubtedly tuberculous, but apparently venereal disease was responsible for the majority. The percentage of old tubal adhesions among the ordinary asylum female population is placed at 12.

It will be remembered that this study of the post-mortem findings was undertaken with the object of discovering what, if any, signs of somatic syphilis were present in cases of general paralysis, in order to support or disprove the theory that this disease is due to a special strain of spirochæte which attacks the nervous tissues only. It has been asserted that the cases which develop general paralysis often have had very slight clinical signs in the primary and secondary stages. One would therefore be led to expect lesions in the somatic system in cases of general paralysis to be but slight, or at any rate to be different from those found in non-nervous cases.

We have shown that somatic lesions do occur in general paralysis, that these are by no means slight, and that they differ in no marked respect from those found in syphilitic cases in general hospitals. These results are of particular interest when it is remembered that although attention has been drawn to the subject by Bolton, in other modern text-books on neurology and psychiatry but scanty mention is made of the presence of somatic lesions in this disease.

Comparison between Syphilis among the Asylum Population and that in the General Community.

The next section of our work deals with the incidence of syphilis among the asylum population as compared with that in the general community. If parenchymatous neuro-syphilis depends upon an inherent weakness of the nervous system then there ought to be a difference in these two figures.

With regard to the incidence of syphilis in the general population a perusal of the literature shows that this is by no means easy to determine. The most extensive and probably the most accurate Wassermann surveys have been made in America, but here the presence of the coloured race complicates matters considerably. Allowance for this factor cannot always be made, since in some of the statistics the author omits to mention whether or not coloured patients were included.

Williams[2] examined clinically and serologically what he calls "a group of individuals representing the great American middle-class population." None of this group, numbering 912 persons, was known or suspected to have syphilis. The percentage of strongly positive Wassermann reactions was 4·4. Vedder[3] reports that in 1916 13 per cent. of 11,933 accepted recruits in the U.S. Army were Wassermann positive, as also were 15 per cent. of 856 candidates for the police force in Washington, and about 5 per cent. of 3203 candidates for commissions in the army. It would appear that in the same locality 5·8 per cent. of hospital admissions showed serological evidence of syphilis. Warthin[4] attacked the problem from a different standpoint. By necropsy study he found that 30 per cent. of bodies showed some pathological evidence of syphilis. This figure may be contrasted with that arrived at by Symmers,[5] who states that post-mortem statistics show that less than 7 per cent. of bodies reveal anatomical evidence of the disease, while in the living subject the Wassermann reaction is positive in over 25 per cent. of all persons investigated. Jeans[6] from the American literature has collected statistics among adults admitted to hospitals and dispensaries (V.D. wards excluded), and his findings may be presented in table form. (Table VIII.)

TABLE VIII.

Town.	Author.	Number of cases.	Number W.R.+	Percentage.
Baltimore ..	Walker	1,080	116	10·8
Boston.. ..	Walker and Haller	4,000	600	15·0
Chicago ..	Moore	418	56	13·4
Ann Arbor ..	Peterson	2,771	160	5·8
San Francisco	Whitney	6,995	518	7·4
	Totals	15,264	1450	9·5

The same author also quotes a Wassermann survey among married pregnant women. The figures are as follows (Table IX.):—

TABLE IX.

Town.	Author.	Number *of cases.*	Percentage of W.R. +
Chicago ..	Falls & Moore	116	10·6
Brooklyn ..	Comminsky	1822	8
Brooklyn ..	Judd	892	7·9
Philadelphia	Williams & Kohner	40	7·5
New York ..	Ottenburg	2488	11·5
	Totals	5358	9·66

Rosenberger,[7] in the Philadelphia General Hospital, states that 4430 blood Wassermann reactions were made during the year 1916. Of these 24·4 per cent. were positive, but, since the hospital has a mental department attached, this figure is probably too high for our purpose.

Much work appears to have been done on the frequency of hereditary syphilis. Perhaps in this connexion the following quotation will suffice: "The amount of hereditary syphilis among the hospital infants and children in four large cities of U.S.A.—New York, St. Louis, San Francisco, and Chicago—appears to range from 2 to 6 per cent." (Churchill and Austin[8]). Very thorough investigations have been carried out upon Panama Canal zone workers by Qualls.[9] The latent syphilitic infection among coloured male employees in this region is extremely high, 23·7 per cent., as compared with 2·3 per cent. among white employees. The total syphilitic infection among white surgical patients was 15 per cent., 981 blood samples being examined. Boudreau,[10] working at Auburn Prison, New York, found that 16·85 per cent. of the males and 33·85 per cent. of the females gave a positive Wassermann reaction.

Without quoting further statistics it will be evident that the percentage of syphilis among the general population is considerable. Thom[11] remarks:—

> "The incidence of syphilis in the United States, including the inherited as well as the acquired form, has been variously estimated at from 10 to 20 per cent. The former is the percentage which I believe to be approximately correct in the white race. In the negro I believe the percentage to be much higher, approximately 30 per cent."

Jeans[6] thinks a figure of 20 per cent. is probably nearer the truth.

Assuming, then, that the incidence of syphilis among the general population is approximately 10 per cent. we now pass to the study of the same problem among asylum inmates. For this purpose the blood and spinal fluid of every new admission to the Lancashire County Mental Hospital, Rainhill, during a period of almost a year were examined by us. Of the 305 cases examined 47 were clinically general paralytics, the diagnosis being confirmed serologically in 42. Of the 258 non-syphilitic psychoses 11·7 per cent. gave a positive Wassermann reaction. The total percentage of syphilis in this institution was, therefore, 23·6, and the figure 11·7 per cent. may be taken as representing the incidence of the disease among the non-paralytic asylum population.

favour the defective durability hypothesis, since such a weakness would naturally occur in several members of the same family. Finally, in this connexion we can find no evidence in support of Mott's contention that social class or type of work play a part in the causation of parenchymatous neurosyphilis.

The results obtained by bacteriologists, which ought to have been the most weighty of all, are, unfortunately, most indefinite. Ever since Noguchi, about 1912, first cultivated the *S. pallidum* many attempts have been made to differentiate strains of the organism depending upon morphological and cultural characteristics and behaviour on inoculation. Some evidence has resulted suggesting that dermotropic and neurotropic strains of the virus exist, but many difficulties have been encountered.

In conclusion, ample evidence of the presence of somatic lesions in general paralysis has been given. These lesions appear to differ in no essential particular from those found in any other form of syphilis, and therefore this fact may be taken as militating against the neurotropic theory of the disease. Support of the defective durability theory is gained by consideration of the family history of general paralytics in respect of hereditary mental weakness, by the death incidence tables of Bolton, and by instances of several members of the same family infected by different persons all developing the same type of parenchymatous neuro-syphilis. If not for this theory, at any rate against the neurotropic school, is the comparative rarity of conjugal general paralysis and tabes.

The evidence concerning syphilis in China and Persia, the examples of dementia paralytica and tabes contracted by different persons from the one source, and the bacteriological evidence, such as it is, favour the neurotropic school. We are of the opinion that the weight of the evidence is in favour of the defective durability hypothesis, whether or not a neurotropic strain of spirochæte exists.

There only remains the pleasant duty of offering our sincere thanks to Dr. E. F. Reeve and the staff of Rainhill Mental Hospital for their enthusiastic support and for their great kindness in collecting a large number of samples under the most difficult and trying conditions. Our thanks are also due to Prof. Ernest Glynn, of Liverpool University, who has given us constant helpful advice and encouragement during this work.

The expenses of a portion of Dr. G. A. Watson's pathological work were defrayed from a grant from the Medical Research Council.

BLOOD-PLATE COUNTS IN PULMONARY TUBERCULOSIS.

By R. G. BANNERMAN, M.D. Edin.,
LATE SENIOR ASSISTANT MEDICAL OFFICER, ENGLISH SANATORIUM, MONTANA, SWITZERLAND.

The relation of blood-plates to microbial infection has been made apparent from a number of different aspects. Bull[1] has shown that the injection of certain bacteria into the circulation of animals is followed by their agglutination and disappearance, and Delrez and Govaerts[2] found that this agglutination is occasioned by the blood-plates. That a diminution of the number of plates is associated with a lowering of the resistance to infection has been proved by Cramer, Drew, and Mottram,[3] who found that thrombopenia could be induced by vitamin-A starvation or appropriate exposure to radium or X radiation, and was associated with a tendency to the development of infective conditions. In the human subject the writer has observed a thrombopenia during acute infection. The following record shows that in pulmonary tuberculosis—a chronic disease—the blood-plate picture is very different, the tendency being to a thrombocytosis.

Technique.

The method described in a previous paper[4] has been greatly improved and simplified as a result of suggestions made by Dr. L. Colebrook. The finger is pricked through a droplet of the diluent with the ragged end of a teated glass pipette whose interior is lined with paraffin: the blood-diluent mixture is then emptied on to a paraffined slide where it is thoroughly mixed by being sucked to and fro by the pipette, and if necessary further diluted: a suitable quantity of a suitable dilution is then placed on a slide, covered, and sealed. In order to conserve a uniform relative distribution of plates and red corpuscles it is essential to carry out the manipulations with rapidity.

Sixty-five cases of pulmonary tuberculosis have been examined in this way; these were unselected but have been rearranged in the table in categories according to the number of plates found; it is believed that the experimental error does not exceed 10 per cent., and in many cases the figure given is the mean of two or more counts. In a series of normal subjects the plate count was found to vary from 250,000 to 380,000 per c.mm., the average being 300,000. All the observations were made at an altitude of 5000 feet, where the normal red corpuscle count is in the region of 6,500,000 per c.mm. The clinical remarks do not aim at any degree of completeness, but are rather intended to give some impression of the cases from a general point of view, with special reference to prognosis: the temperatures (T.) mentioned are Fahrenheit and rectal. G.C. refers to the general condition as evidenced by weight, exercise tolerance, and appetite. Treatment by artificial pneumothorax is denoted by A.P.

Discussion.

It is apparent that the blood-plates are generally present in excessive numbers in active pulmonary tuberculosis, and that, broadly speaking, the more serious the clinical condition the greater is the degree of thrombocytosis. All the fatal cases in the series are to be found in Category III. In some cases, where repeated counts have been made at intervals, a change in the number of plates has occurred—e.g., Nos. 35, 38, 60, 65. When this change is in the direction of the normal, it has coincided with an improvement in the clinical condition, whereas a movement in the opposite direction, or the persistence of a high plate count, has been associated with progression of the disease. On the other hand, the maintenance of a normal plate count points to stability. More prolonged observation is required to determine the more precise relations between thrombocytosis and the stage of the disease, but it is already apparent that there is no necessary correspondence between the number of plates and such features as pyrexia, the anatomical extent of the

It is interesting to compare these figures with those obtained in similar institutions in America. Fell,[12] working in the Elgin State Hospital, found a positive Wassermann reaction in 15·7 per cent. of 1266 consecutive admissions. Excluding the syphilitic psychoses the figure obtained by him dropped to 4·8 per cent. Lowrey[13] examined 1600 unselected admissions to Danvers State Hospital, and found that 16 per cent. gave a definitely positive and 3·8 per cent. a doubtfully positive Wassermann reaction. Of Holbrook's[14] 1153 white patients in the East Louisiana Hospital for the Insane only 6 per cent. of the bloods reacted positively, while amongst 447 negroes a figure of 9 per cent. was registered. Flashman and Latham[15] have studied the same problem amongst idiots and imbeciles. At Newcastle Hospital they obtained 9·8 per cent. of positive reactions (436 cases examined). Interesting quotations are to be found in this paper dealing with similar cases in other areas. (Table X.)

Table X.

	Cases.	Per cent.
Robiart and others	246	30·8
Kellner and others	216	7·4
Liepmann	78	9·0
Dean	330	15·4
Dalldorf Asylum	—	13·2

It is to be regretted that, with the exception of Fell, these authors do not draw a distinction between the paralytic and non-paralytic elements of the asylum population. In Fell's work the figure (4·8 per cent.) for Elgin State Hospital (general paralytics excluded) is distinctly below the average. At Rainhill Mental Hospital we obtained a figure of 11·7 per cent. At first sight, if the "defective durability" theory be true, one would expect to find the incidence of syphilis in mental hospitals, when the general paralytics are excluded, to be practically nil, except for comparatively recent infections in young subjects; for every individual who is a potential lunatic should, if he contracted syphilis, become a general paralytic. Further consideration of this question, however, must lead to the view that it is not every potential lunatic who is likely to develop general paralysis, but only one whose mental weakness takes the form of a tendency to dementia—such a person has been called by Bolton[1] a "dementable psychopath." Should a person belonging to this group of dementable psychopaths acquire syphilis he should develop general paralysis. Therefore, the incidence of syphilis among cases of dementia, other than dementia paralytica, in any asylum should be much lower than that among other asylum inmates or in the general community.

In order to test this hypothesis we examined the blood with regard to the Wassermann reaction in 198 cases of secondary dementia at the Lancashire County Mental Hospital, Rainhill. Of these 198 cases seven gave a positive reaction, a percentage of 3·5; this figure is low as compared with that for the general asylum population (11·9) and gives support to this theory.

Facts Collected from the Literature.

The last section of this paper deals with facts germane to the subject which have been collected from the literature, but have not, as yet, been confirmed by us. Bolton[1] has published very careful work on this subject. He states that—

> "The ordinary sane individual and the ordinary psychopath or potential lunatic who possesses cortical neurones of average durability may suffer from syphilis with impunity as regards the onset of dementia paralytica; and I should express the same opinion with regard to syphilised lunatics with little or no dementia, who are fairly common in asylums. On the other hand, I think that a psychopath, who possesses cortical neurones of subnormal durability, and who apart from an attack of syphilis would develop a moderate grade of dementia, . . . would on acquiring this disease be liable sooner or later to suffer from one or other of the types of dementia paralytica."

In order to prove this contention Bolton investigated the question as to whether or no insanity or family degeneracy is to be found in the parents or relatives of general paralytics. He collected the family histories of 85 cases. He summarises his results as follows:—

> "Of the cases 13 were private and 72 rate-paid patients. In eight of the 13 private cases there was direct or collateral insanity; in three more there were allied disorders, including epilepsy; in the twelfth the father died of cerebral hæmorrhage and the mother of paralysis . . .; and in the thirteenth the mother and sister died of phthisis, a brother was delicate, and 11 out of 14 in the family were dead. . . . Of the 72 histories of rate-paid patients, there was psychopathic heredity in no less than 81·9 per cent., and an abnormally high family death-rate in another 9·7 per cent."

These findings certainly appear to lend support to the defective neuronic durability theory.

On the other hand, evidence in favour of the neurotropic theory is gathered from a consideration of statistics of neuro-syphilis incidence among certain races. Lennox[16] showed that in China syphilis is three times more common than in America, whereas the incidence of neuro-syphilis is extremely rare; and, moreover, that those cases which do show signs of neuro-syphilis are usually sailors who have been infected from European sources. In our series of cases there were 13 Chinamen, eight of whom were general paralytics. Christidi[17] has shown that among 3000 cases of syphilis in Persia general paralysis was not found once, although the Persians are intellectual workers and use alcohol and opium. Further, Europeans infected by Persians show the same immunity to neuro-syphilis; but of 22 Europeans infected by non-Persian women two developed general paralysis.

Against this should be placed the figures derived from a study of conjugal general paralysis and tabes. Drysdale[18] analysed the literature up to the year 1916 in this respect, and was only able to collect 44 published cases where man and wife were both infected with parenchymatous neuro-syphilis. So far as we could gather two such instances occurred in our series.

Another argument against the neurotropic theory is the fact that general paralysis is relatively uncommon in women. If there were a neurotropic strain of spirochæte one would expect a larger number of female cases, since it may be assumed that probably every syphilitic man runs the risk of infecting at least one woman. The same argument is applicable in the case of the children of general paralytics in whom congenital somatic syphilis is very common and yet neuro-syphilis is rare. It should be mentioned, however, that in the records of a series of juvenile paretics numbering 12, one of the parents died of general paralysis in two instances (Watson[20]).

It is difficult to understand how a special neurotropic variety of spirochæte, having its only habitat in the nervous system, can enter another host. But that this is not necessarily true is suggested by the work of Moore and Kemp,[19] who state:—

> "Although the danger of infection for the spouse increases as the date of infection of the one acquiring syphilis approaches the year of marriage, it is shown that neurosyphilitic patients may be infectious for many years in spite of the absence of demonstrable open lesions."

Many classical examples are found in the literature of instances of one woman infecting many men in all of whom a similar parenchymatous neuro-syphilis has resulted. These observations provide one of the most important planks in the platform of the neurotropic school. On the other hand, just as many, or more, instances are found in the literature where several members of the same family, infected at widely different times by different women in different countries, have all developed the same variety of parenchymatous neuro-syphilis. These observations favour the defective durability hypothesis, since such a weakness would naturally occur in several members of the same family. Finally, in this connexion we can find no evidence in support of Mott's contention that social class or type of work play a part in the causation of parenchymatous neuro-syphilis.

The results obtained by bacteriologists, which ought to have been the most weighty of all, are, unfortunately, most indefinite. Ever since Noguchi, about 1912, first cultivated the *S. pallidum* many attempts have been made to differentiate strains of the organism depending upon morphological and cultural characteristics and behaviour on inoculation. Some evidence has resulted suggesting that dermotropic and neurotropic strains of the virus exist, but many difficulties have been encountered.

In conclusion, ample evidence of the presence of somatic lesions in general paralysis has been given. These lesions appear to differ in no essential particular from those found in any other form of syphilis, and therefore this fact may be taken as militating against the neurotropic theory of the disease. Support of the defective durability theory is gained by consideration of the family history of general paralytics in respect of hereditary mental weakness, by the death incidence tables of Bolton, and by instances of several members of the same family infected by different persons all developing the same type of parenchymatous neuro-syphilis. If not for this theory, at any rate against the neurotropic school, is the comparative rarity of conjugal general paralysis and tabes.

The evidence concerning syphilis in China and Persia, the examples of dementia paralytica and tabes contracted by different persons from the one source, and the bacteriological evidence, such as it is, favour the neurotropic school. We are of the opinion that the weight of the evidence is in favour of the defective durability hypothesis, whether or not a neurotropic strain of spirochæte exists.

There only remains the pleasant duty of offering our sincere thanks to Dr. E. F. Reeve and the staff of Rainhill Mental Hospital for their enthusiastic support and for their great kindness in collecting a large number of samples under the most difficult and trying conditions. Our thanks are also due to Prof. Ernest Glynn, of Liverpool University, who has given us constant helpful advice and encouragement during this work.

The expenses of a portion of Dr. G. A. Watson's pathological work were defrayed from a grant from the Medical Research Council.

BLOOD-PLATE COUNTS IN PULMONARY TUBERCULOSIS.

BY R. G. BANNERMAN, M.D. EDIN.,
LATE SENIOR ASSISTANT MEDICAL OFFICER, ENGLISH SANATORIUM, MONTANA, SWITZERLAND.

THE relation of blood-plates to microbial infection has been made apparent from a number of different aspects. Bull[1] has shown that the injection of certain bacteria into the circulation of animals is followed by their agglutination and disappearance, and Delrez and Govaerts[2] found that this agglutination is occasioned by the blood-plates. That a diminution of the number of plates is associated with a lowering of the resistance to infection has been proved by Cramer, Drew, and Mottram,[3] who found that thrombopenia could be induced by vitamin-A starvation or appropriate exposure to radium or X radiation, and was associated with a tendency to the development of infective conditions. In the human subject the writer has observed a thrombopenia during acute infection. The following record shows that in pulmonary tuberculosis—a chronic disease—the blood-plate picture is very different, the tendency being to a thrombocytosis.

Technique.

The method described in a previous paper[4] has been greatly improved and simplified as a result of suggestions made by Dr. L. Colebrook. The finger is pricked through a droplet of the diluent with the ragged end of a teated glass pipette whose interior is lined with paraffin: the blood-diluent mixture is then emptied on to a paraffined slide where it is thoroughly mixed by being sucked to and fro by the pipette, and if necessary further diluted: a suitable quantity of a suitable dilution is then placed on a slide, covered, and sealed. In order to conserve a uniform relative distribution of plates and red corpuscles it is essential to carry out the manipulations with rapidity.

Sixty-five cases of pulmonary tuberculosis have been examined in this way; these were unselected but have been rearranged in the table in categories according to the number of plates found; it is believed that the experimental error does not exceed 10 per cent., and in many cases the figure given is the mean of two or more counts. In a series of normal subjects the plate count was found to vary from 250,000 to 380,000 per c.mm., the average being 300,000. All the observations were made at an altitude of 5000 feet, where the normal red corpuscle count is in the region of 6,500,000 per c.mm. The clinical remarks do not aim at any degree of completeness, but are rather intended to give some impression of the cases from a general point of view, with special reference to prognosis: the temperatures (T.) mentioned are Fahrenheit and rectal. G.C. refers to the general condition as evidenced by weight, exercise tolerance, and appetite. Treatment by artificial pneumothorax is denoted by A.P.

Discussion.

It is apparent that the blood-plates are generally present in excessive numbers in active pulmonary tuberculosis, and that, broadly speaking, the more serious the clinical condition the greater is the degree of thrombocytosis. All the fatal cases in the series are to be found in Category III. In some cases, where repeated counts have been made at intervals, a change in the number of plates has occurred—e.g., Nos. 35, 38, 60, 65. When this change is in the direction of the normal, it has coincided with an improvement in the clinical condition, whereas a movement in the opposite direction, or the persistence of a high plate count, has been associated with progression of the disease. On the other hand, the maintenance of a normal plate count points to stability. More prolonged observation is required to determine the more precise relations between thrombocytosis and the stage of the disease, but it is already apparent that there is no necessary correspondence between the number of plates and such features as pyrexia, the anatomical extent of the

It is interesting to compare these figures with those obtained in similar institutions in America. Fell,[12] working in the Elgin State Hospital, found a positive Wassermann reaction in 15·7 per cent. of 1266 consecutive admissions. Excluding the syphilitic psychoses the figure obtained by him dropped to 4·8 per cent. Lowrey[13] examined 1600 unselected admissions to Danvers State Hospital, and found that 16 per cent. gave a definitely positive and 3·8 per cent. a doubtfully positive Wassermann reaction. Of Holbrook's[14] 1153 white patients in the East Louisiana Hospital for the Insane only 6 per cent. of the bloods reacted positively, while amongst 447 negroes a figure of 9 per cent. was registered. Flashman and Latham[15] have studied the same problem amongst idiots and imbeciles. At Newcastle Hospital they obtained 9·8 per cent. of positive reactions (436 cases examined). Interesting quotations are to be found in this paper dealing with similar cases in other areas. (Table X.)

TABLE X.

	Cases.	Per cent.
Robiart and others	246	30·8
Kellner and others	216	7·4
Liepmann	78	9·0
Dean	330	15·4
Dalldorf Asylum	—	13·2

It is to be regretted that, with the exception of Fell, these authors do not draw a distinction between the paralytic and non-paralytic elements of the asylum population. In Fell's work the figure (4·8 per cent.) for Elgin State Hospital (general paralytics excluded) is distinctly below the average. At Rainhill Mental Hospital we obtained a figure of 11·7 per cent. At first sight, if the "defective durability" theory be true, one would expect to find the incidence of syphilis in mental hospitals, when the general paralytics are excluded, to be practically nil, except for comparatively recent infections in young subjects; for every individual who is a potential lunatic should, if he contracted syphilis, become a general paralytic. Further consideration of this question, however, must lead to the view that it is not every potential lunatic who is likely to develop general paralysis, but only one whose mental weakness takes the form of a tendency to dementia—such a person has been called by Bolton[1] a "dementable psychopath." Should a person belonging to this group of dementable psychopaths acquire syphilis he should develop general paralysis. Therefore, the incidence of syphilis among cases of dementia, other than dementia paralytica, in any asylum should be much lower than that among other asylum inmates or in the general community.

In order to test this hypothesis we examined the blood with regard to the Wassermann reaction in 198 cases of secondary dementia at the Lancashire County Mental Hospital, Rainhill. Of these 198 cases seven gave a positive reaction, a percentage of 3·5; this figure is low as compared with that for the general asylum population (11·9) and gives support to this theory.

Facts Collected from the Literature.

The last section of this paper deals with facts germane to the subject which have been collected from the literature, but have not, as yet, been confirmed by us. Bolton[1] has published very careful work on this subject. He states that—

> "The ordinary sane individual and the ordinary psychopath or potential lunatic who possesses cortical neurones of average durability may suffer from syphilis with impunity as regards the onset of dementia paralytica; and I should express the same opinion with regard to syphilised lunatics with little or no dementia, who are fairly common in asylums. On the other hand, I think that a psychopath, who possesses cortical neurones of subnormal durability, and who apart from an attack of syphilis would develop a moderate grade of dementia, . . . would on acquiring this disease be liable sooner or later to suffer from one or other of the types of dementia paralytica."

In order to prove this contention Bolton investigated the question as to whether or no insanity or family degeneracy is to be found in the parents or relatives of general paralytics. He collected the family histories of 85 cases. He summarises his results as follows:—

> "Of the cases 13 were private and 72 rate-paid patients. In eight of the 13 private cases there was direct or collateral insanity; in three more there were allied disorders, including epilepsy; in the twelfth the father died of cerebral hæmorrhage and the mother of paralysis . . .; and in the thirteenth the mother and sister died of phthisis, a brother was delicate, and 11 out of 14 in the family were dead. . . . Of the 72 histories of rate-paid patients, there was psychopathic heredity in no less than 81·9 per cent., and an abnormally high family death-rate in another 9·7 per cent."

These findings certainly appear to lend support to the defective neuronic durability theory.

On the other hand, evidence in favour of the neurotropic theory is gathered from a consideration of statistics of neuro-syphilis incidence among certain races. Lennox[16] showed that in China syphilis is three times more common than in America, whereas the incidence of neuro-syphilis is extremely rare; and, moreover, that those cases which do show signs of neuro-syphilis are usually sailors who have been infected from European sources. In our series of cases there were 13 Chinamen, eight of whom were general paralytics. Christidi[17] has shown that among 3000 cases of syphilis in Persia general paralysis was not found once, although the Persians are intellectual workers and use alcohol and opium. Further, Europeans infected by Persians show the same immunity to neuro-syphilis; but of 22 Europeans infected by non-Persian women two developed general paralysis.

Against this should be placed the figures derived from a study of conjugal general paralysis and tabes. Drysdale[18] analysed the literature up to the year 1916 in this respect, and was only able to collect 44 published cases where man and wife were both infected with parenchymatous neuro-syphilis. So far as we could gather two such instances occurred in our series.

Another argument against the neurotropic theory is the fact that general paralysis is relatively uncommon in women. If there were a neurotropic strain of spirochæte one would expect a larger number of female cases, since it may be assumed that probably every syphilitic man runs the risk of infecting at least one woman. The same argument is applicable in the case of the children of general paralytics in whom congenital somatic syphilis is very common and yet neuro-syphilis is rare. It should be mentioned, however, that in the records of a series of juvenile paretics numbering 12, one of the parents died of general paralysis in two instances (Watson[20]).

It is difficult to understand how a special neurotropic variety of spirochæte, having its only habitat in the nervous system, can enter another host. But that this is not necessarily true is suggested by the work of Moore and Kemp,[19] who state:—

> "Although the danger of infection for the spouse increases as the date of infection of the one acquiring syphilis approaches the year of marriage, it is shown that neurosyphilitic patients may be infectious for many years in spite of the absence of demonstrable open lesions."

Many classical examples are found in the literature of instances of one woman infecting many men in all of whom a similar parenchymatous neuro-syphilis has resulted. These observations provide one of the most important planks in the platform of the neurotropic school. On the other hand, just as many, or more, instances are found in the literature where several members of the same family, infected at widely different times by different women in different countries, have all developed the same variety of parenchymatous neuro-syphilis. These observations favour the defective durability hypothesis, since such a weakness would naturally occur in several members of the same family. Finally, in this connexion we can find no evidence in support of Mott's contention that social class or type of work play a part in the causation of parenchymatous neurosyphilis.

The results obtained by bacteriologists, which ought to have been the most weighty of all, are, unfortunately, most indefinite. Ever since Noguchi, about 1912, first cultivated the *S. pallidum* many attempts have been made to differentiate strains of the organism depending upon morphological and cultural characteristics and behaviour on inoculation. Some evidence has resulted suggesting that dermotropic and neurotropic strains of the virus exist, but many difficulties have been encountered.

In conclusion, ample evidence of the presence of somatic lesions in general paralysis has been given. These lesions appear to differ in no essential particular from those found in any other form of syphilis, and therefore this fact may be taken as militating against the neurotropic theory of the disease. Support of the defective durability theory is gained by consideration of the family history of general paralytics in respect of hereditary mental weakness, by the death incidence tables of Bolton, and by instances of several members of the same family infected by different persons all developing the same type of parenchymatous neuro-syphilis. If not for this theory, at any rate against the neurotropic school, is the comparative rarity of conjugal general paralysis and tabes.

The evidence concerning syphilis in China and Persia, the examples of dementia paralytica and tabes contracted by different persons from the one source, and the bacteriological evidence, such as it is, favour the neurotropic school. We are of the opinion that the weight of the evidence is in favour of the defective durability hypothesis, whether or not a neurotropic strain of spirochæte exists.

There only remains the pleasant duty of offering our sincere thanks to Dr. E. F. Reeve and the staff of Rainhill Mental Hospital for their enthusiastic support and for their great kindness in collecting a large number of samples under the most difficult and trying conditions. Our thanks are also due to Prof. Ernest Glynn, of Liverpool University, who has given us constant helpful advice and encouragement during this work.

The expenses of a portion of Dr. G. A. Watson's pathological work were defrayed from a grant from the Medical Research Council.

When this change is in the direction of the normal, it has coincided with an improvement in the clinical condition, whereas a movement in the opposite direction, or the persistence of a high plate count, has been associated with progression of the disease. On the other hand, the maintenance of a normal plate count points to stability. More prolonged observation is required to determine the more precise relations between thrombocytosis and the stage of the disease, but it is already apparent that there is no necessary correspondence between the number of plates and such features as pyrexia, the anatomical extent of the

a gradual fall in the leucocytes to normal, following weekly doses of X rays over a period of about three months. It has been shown that in healthy people small doses of X rays give rise to an increase in the platelet count (Degkwitz), the red and white cells being little affected. Larger doses, however, lead to a destruction of the platelet; in fact, Fabricius Möller[12] was able to produce typical purpura hæmorrhagica, with a marked fall in the platelet count, by exposing guinea-pigs to X rays.

Most of the cases of broncho-pneumonia showed an increase of platelets, though one case showed a definite fall. Other observers have found a preliminary fall during the onset of acute disease, followed by a rise during convalescence. Hæmorrhagic spots simulating purpura were present on the legs and abdomen of one case of broncho-pneumonia, with a platelet count of 812,000. This child was dangerously ill, and apparently suffering from severe septicæmia, so that the hæmorrhagic foci were probably due to septic thrombi in the capillaries. These findings correspond very closely with those obtained by previous workers, though Buckman and Habiser report one case of lymphatic leukæmia with normal platelet count and bleeding time. Generally speaking, an increase of platelets is associated with an active proliferation of bone marrow, a diminution of these elements being associated with bone-marrow failure. The marked increase of platelets after splenectomy, which has also been shown experimentally by Bedson (findings as yet unpublished), indicates that the spleen is concerned with their destruction, and negatives the theory that they are formed by the reticulo-endothelial system.

The increase of platelets in lymphadenoma is of interest in connexion with the proliferation of lymphadenoma giant cells. Two of these cases were examined post mortem, and sections of the bone marrow (femur) showed proliferation of megalocaryocytes. In one case especially, which had a platelet count of over a million, numerous young megalocaryocytes were present. In many cases these were difficult to distinguish from giant lymphadenoma cells, both presenting clear vesicular lobed nuclei with well-marked nucleoli, and irregular, badly defined, pale-staining cytoplasm. The bone marrow from several cases of broncho-pneumonia in young children was also examined and showed numerous megalocaryocytes, some young forms being present, which again presented a striking resemblance to the lymphadenoma cell. As the megalocaryocyte gets older, it grows much larger, the nucleus becomes multi-lobed, stains more darkly, is less vesicular, and does not show nucleoli so distinctly; in the terminal stages pyknotic forms are seen. Such changes have not been met with in the lymphadenoma cell.

Correlation with Coagulation.

In nearly all of the above cases of blood diseases the bleeding time and coagulation time were tested. The bleeding time was estimated by the method described by Duke[1] (loc. cit.). A standard wound was made in the lobe of the ear with puncturing apparatus (B 2216), as supplied by Baird and Tatlock, and each drop of blood, as it exuded, absorbed with filter-paper at intervals of about 15 seconds, avoiding touching the ear, until the bleeding stopped. Normally the bleeding time varies from 2 to 3½ minutes. Coagulation time was estimated by Rodda's[13] method, which, though a rough bedside test, gives more consistent results than any of the coagulometer methods. A drop of blood is taken direct into a clean watch-glass, a grain of No. 6 shot added, and then covered with another watch-glass to prevent evaporation. The glass is now turned from side to side through an angle of 90°, so that the drop of blood runs out into a streak about three-quarters of an inch long. The glass is gently rocked from side to side at intervals of half a minute, the grain of shot rolling to and fro in the drop of blood until coagulation occurs, when it is held by the clot. Normal coagulation time with this method varies from 5 to 10 minutes. In each case a control should be done.

In all the cases tested no direct correlation could be found between the platelet count, bleeding time, and coagulation time. The bleeding time was, however, usually prolonged when the platelets were markedly diminished. The coagulation time appeared to be quite independent of the number of platelets and would seem a very unreliable guide, with regard to tendency to hæmorrhage, apart from cases of hæmophilia, in which the bleeding time and platelets are stated to be approximately normal while the coagulation time is definitely prolonged.

Conclusions.

(1) A considerable diminution in the platelet count was found in pernicious anæmia, lymphatic leukæmia, and purpura hæmorrhagica, whereas an increase in these elements of the blood was noted in lymphadenoma and myelogenous leukæmia.

(2) In those cases of secondary anæmia examined, normal or slightly increased counts were obtained.

(3) Generally speaking, an increase of platelets would seem to be associated with a hyperactivity of the bone marrow and vice versa, suggesting that the platelet originates in this portion of the hæmopoietic system.

(4) In one case examined, splenectomy resulted in a very considerable increase in the platelet count.

(5) An increased bleeding time is associated with a low platelet count.

(6) No correlation could be made out between bleeding time and coagulation time.

I have to thank Dr. S. P. Bedson for his valuable suggestions and criticisms in connexion with this work, and also the visiting staff of the Royal Victoria Infirmary, Newcastle-on-Tyne, and of the East London Hospital, Shadwell, for free access to the cases under their charge.

(Continued at foot of next page.)

HOP DERMATITIS.

BY W. J. O'DONOVAN, M.D., M.R.C.P. LOND.,
FIRST ASSISTANT IN THE SKIN DEPARTMENT, LONDON HOSPITAL.

ALTHOUGH the annual migration of large numbers of the poor of the East End has long been an established factor in the social life of these workers, and although hopping annually for a fortnight to a month makes breaches in the attendances of out-patients in every department of the London Hospital, dermatitis due to hops has not hitherto been noted in the skin department. Several reasons may be advanced for this, particularly the fact that hopping is regarded as a holiday and never as a serious occupation, and also because there is reason to believe that the condition itself is rare and that the factors favourable for its development are not always present. The condition itself is so severe that patients of years of discretion who find that they cannot go among the hops are more likely to avoid exposure entirely rather than, by suffering repeated attacks, to bring this condition to the notice of our profession.

Literature.

Dermatological literature is singularly unhelpful. Macleod[1] states that "about a hundred plants have actually been found capable of setting up dermatitis and their number is gradually increasing, especially from abroad," but in this connexion the English hop is not mentioned. Prosser White,[2] merely includes "Nat. Order Cannabinaceæ, Hops when picked," among causes of plant dermatitis. Dale,[3] in his "Pharmacologia," referring to the external application of hops, says only, De Lupulo Salictario—"Extrinsicus sedebat dolores." This attribute of 1693 is to be found again in 1916 in Squire's[4] "Companion to the Pharmacopœia," which says that hops may be used topically as fomentation or poultice in painful inflammations and swellings. The latest Codex[5] mentions that the hop strobiles contain an essential oil called humulene that is a sesquiterpene. Danlos,[6] whose case (1900) I quote, later makes mention of a barren search of the literature for a similar case. In the 1923 edition of Bernhard Smith's "Poisonous Plants of All Countries," humulus lupulus is not mentioned. Dr. John Badham,[7] writing from Worksop, Notts, in October, 1834, describes fully the case of a girl, Mary Bell, aged 14. He gives a reason for his writing "as I have not been able to find a case of the kind recorded by any authors, English or foreign." His patient attributed her symptoms to immersing her hands, then suffering with chilblains, in a hop-bin to warm them. Shortly after this she began to feel a smarting or tingling in the hands as if she had been stung by nettles. In a few hours a distinct cuticular efflorescence appeared accompanied by a *strong disposition to sleep;* vision was impaired and she fell into profound slumber. The morning after her face was covered with a deep erythema, her eyelids were closed by tumefaction, by the evening the hands and face were covered with vesicles, and in four more days the patient was desquamating and convalescing. "The interest of this case appears to consist, first in its appearing to prove the physiological fact of cutaneous absorption; and second because it discovers a new and hitherto unsuspected acrid principle in the hop."

FIG. 1 (CASE 1).

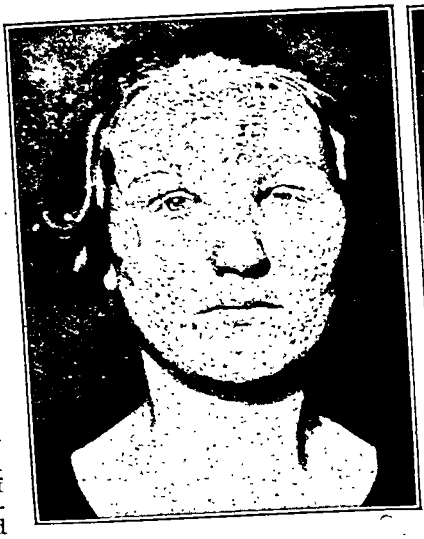

FIG. 2 (CASE 2).

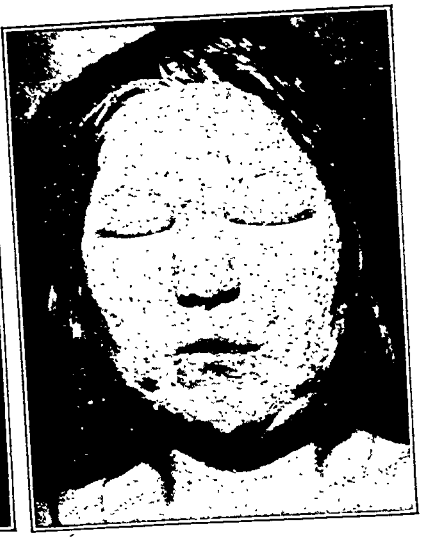

Two cases of hop dermatitis, both occurring in the same patient for the second time.

Danlos's reference[6] to the condition is as follows:—

Eczéma artificiel provoqué par le houblon.—Il s'agit d'une femme de 67 ans, entrée à l'hôpital avec un eczéma typique de la figure (gonflement des paupières et des joues, vésiculation abondante) et de la face dorsale des mains (vésicules groupées, sous-épidermiques, confluentes); la malade nous dit que les accidents se produisent chez elle pour la seconde fois dans les mêmes circonstances. Il y a cinq ans, c'est après avoir été occupée pendant un mois à tirer du houblon qu'elle a vu se développer l'éruption. Cette fois, c'est après deux jours seulement de travail que le mal est apparu. "Cinq autres femmes, employées au même travail, avaient présenté de semblables accidents."

Sabouraud and other distinguished French dermatologists concurred in the writer's diagnosis of his case.

Case Records.

The following two cases were recently admitted as out-patients to the London Hospital.

CASE 1.—E. B., aged 20, a usually healthy blonde, first went hopping when a girl of 12 and was laid up then with erysipelas of the face. For the second time in her life she, this year, again went hopping in Kent, and her face itched as soon as she entered the hop-field. She gave up at the end of the day and appeared at the skin clinic of the London Hospital on Sept. 4th, 1924, with an eruption of four days' standing which had been diagnosed as erythema solare! Her face was red and swollen, the eyelids were markedly distended with œdema, and the affected skin was covered with small, often broken, vesicles. There was no adenitis, no conjunctival congestion, no pityriasis capitis, no focus of purulent inflammation, and no fever. She complained only of the deformity, the itching, and the tightness of the skin of her face. When seen again in five days she was almost well. (Fig. 1.)

CASE 2.—A. B., aged 16, was also a blonde. She remembered no recent illness and appeared at Dr. J. H. Sequeira's clinic on the same morning as the previous case, being sent to us as a case of urticaria. She had travelled to visit

relations in the hop-fields on Monday; on Tuesday her "forehead broke out in pimples," on Wednesday her whole face was swollen, and on Thursday, Sept. 4th, 1924, she was led to the hospital by her mother, unable to see. The patient's face was red and very swollen, the surface papular and moist, her eyes were occluded by œdema of the lids. on her neck were numerous small and large discrete red papules. On her forearms were several discrete red papules and many red raised linear abrasions up to four inches long, due to scratches by the hop bine. When seen again in five days all swelling was gone and the skin was clear, save for small scabs on the chin. It is noteworthy that this patient, too, when aged 12, as in the case of E. B., was brought to the hospital from the hop-fields on Sept. 28th, 1920, for what was then termed impetigo of the face and arms, and was apparently cured after two visits. (Fig. 2.)

Summary.

In a characteristic case of plant poisoning the hands, face, and genitals are covered with closely placed minute vesicles and bullæ on an erythematous base. There is often considerable tumefaction. The eruption is often mistaken for erysipelas, but its appearance in gardeners (amateurs or professional) should lead to careful inquiry as to the possibility of plant poisoning.[4] It can be seen that the cases I have described follow closely the general type-reaction as described by Sequeira. Females only, so far, have been affected, from the ages of 12 up to 67, always in the month of *September*. The eruption is severe and recurs rapidly on re-exposure. The diagnoses that have been so far suggested, before the occupational ætiology was appreciated, were impetigo, erysipelas, hydroa, and urticaria.

THE VITAMIN-A CONTENT OF CERTAIN VEGETABLE OILS.

BY ARTHUR DIGHTON STAMMERS, B.A. CAMB.,

SENIOR LECTURER IN PHYSIOLOGY, UNIVERSITY OF THE WITWATERSRAND, JOHANNESBURG.

THE following are notes of some experiments, carried out at the Nutrition Laboratory, Port Sunlight, on the vitamin-A content of certain oils.

I. *Arachis and Linseed Oils.*

Drummond and Coward (1920)[1] have reported that the amount of vitamin A in vegetable oils depends (*a*) upon the source from which the oil is derived, and (*b*) upon the method of preparation and refinement. They also found that linseed oil was not entirely destitute of vitamin A unless it had been reduced, in which case the vitamin was lost. The linseed oil used was cold drawn from whole seeds, and not having been subjected to any drastic methods of refinement, would consequently be expected to retain any vitamin originally present.

The usual method of preparing arachis oil is by cold drawing from dried seeds. This produces the finest quality. A second grade may be obtained by moistening and heating the residue from the former process. It is refined by allowing it to stand for some time and filtering the supernatant liquid. The latter is afterwards treated with fullers' earth and animal charcoal which bleaches it (and possibly removes some of the vitamin which may become absorbed). In the sample I used, the nuts, previous to being cold drawn, had been decorticated. and this might be expected to have a deleterious effect upon the vitamin-B content of the oil, since it is to be supposed that, as in the case of other seeds, this vitamin is localised in the pericarp. The absence of any vitamin B from the oil, however, would have been made up in the food of the animals under experiment by the addition of the marmite extract used, and consequently one would not have expected the growth of the animals to be impaired on this account. Mellanby[2] has found that arachis oil is protective against rickets, but, beyond this, there is little that can be found in the literature as regards its vitamin content.

Technique.

The technique of the experiments was as described previously (Stammers, 1921),[3] eight animals being used for each experiment and eight as controls, fed on basal diet plus butter fat. The experiments were carried out under winter conditions, so that the growth from butter fat was not as good as otherwise might be expected. They were continued for 101 days. At the commencement the average weights were as follows :—

Linseed oil animals	53 g.
Arachis „ „	54 g.
Butter fat (controls)..	57 g.

and at the conclusion :

Linseed oil animals	74 g.
Arachis „ „	61 g.
Controls	146 g.

The gain in weight over this experimental period, therefore, was :

Linseed oil animals	21 g.
Arachis „ „	7 g.
Controls	89 g.

Four of the linseed oil and three of the arachis oil animals died before the twenty-eighth day of the experiment, after exhibiting symptoms of some infection of the urogenital tract[4] and considerable distension of the abdomen. The latter, on post-mortem examination, proved to be due to the intestines being inflated with gas. These animals must, therefore, be left out of account, as their deaths were not, in all probability, due to any deficiency of vitamins in the diet. In this connexion, it is noteworthy that five of the butter fat controls also succumbed before the thirtieth day, apparently from the same cause as the others, as their symptoms were identical. Consequently, after this period, the growth is judged upon four linseed oil animals, five arachis oil, and three butter fat, and the results must therefore be considered in the light of this. Of the remaining animals, two of those fed on linseed oil died on the ninety-fifth day, and there remained two survivors after the termination of the experiment, which, although apparently in very poor condition, had not developed ophthalmia.

Of those fed on arachis oil, three died (on the fifty-seventh, sixty-fourth, and seventy-first days) before the conclusion of the experiment, thus leaving two survivors, both of which exhibited marked signs of ophthalmia. The three controls on butter fat remained in good condition, although their growth was subnormal.

Summary and Conclusions.

The survivors from the linseed oil experiment, although in very poor condition, did not develop ophthalmia, while those from arachis oil did, in a marked degree. This may be due to individual predisposing causes. It is difficult, however, to reconcile this with Mellanby's finding that arachis oil is protective against rickets.

It is concluded that neither of these oils, prepared in the way described, which would probably be the best possible as regards preserving the original vitamin-A content, is of any value as a source of this vitamin.

II. *Maize Oil.*

Two experiments on this product are described. The sample used in the first of these had been in the laboratory for some months and was rancid; it was therefore expected that the vitamin content might have become impaired through oxidation.

The experiment was commenced on Nov. 19th, 1920, and was carried on for 101 days, eight animals (rats) being used with eight controls and the ordinary technique of feeding, weighing, &c., being employed (Stammers, 1921).[3] At the commencement the animals averaged 54 g. in weight, which is about 18 g. above the normal for their ages, and they maintained a superiority to the normal for over three weeks. At the end of the experimental period the average weight was 128·5 g. Three animals died during the course of the experiment, but of these two were due to some unascertained cause and took place before the twenty-fourth day of the experiment. The survivors maintained an excellent state of health up to the end of the experiment, and the growth observed, although showing a considerable falling-off from the normal, yet bears very favourable comparison with that obtained from butter prepared during the winter. As an example of this the following table may be interesting.

The control fat used in this experiment was steam-distilled palm kernel oil (Stammers, 1921)[5] and the animals used as controls averaged 56 g. in weight at the beginning and 53 g. at the end, the maximum average attained being 76 g.

Experimental fat.	Date begins.	Date ends.	No. of days.	Total gain in weight.
Butterfat	12/10/20	21/1/21	101	88 g.
,, ,,	19/10/20	28/1/21	101	75 g.
,, ,,	2/11/20	11/2/21	101	85 g.
Maize oil.	19/11/20	28/2/21	101	75 g.

The second experiment was commenced on April 19th, 1921, and was terminated after 59 days. A sample of fresh maize oil was used which had been refined so that it was tasteless and almost odourless. The oil was pale amber in colour as compared with that used in the first experiment, which was very dark.

The same number of animals both for control and experiment was used as before, and the average weight of both experimental and control animals was 48 g. Steam-distilled palm kernel oil was again used as the control fat. At the conclusion of the experiment the average weight of the experimental animals was 148 g., and of the controls 88 g. The rats were slightly heavier than the normal at the commencement, and they maintained a superiority throughout, although it was somewhat diminished towards the end. During the experiment the animals appeared to be in excellent health and there was no mortality, except among the controls, three of which died after exhibiting symptoms of ophthalmia and general ill-health.

Summary and Conclusions.

Experiments with two samples of maize oil, one crude and rancid and one refined, indicate that the vitamin-A content is high. It compares very favourably with palm oil and with winter butter fat. During the second experiment a concurrent test upon cod-liver oil was being carried on, and the growth from this sample of maize oil showed some superiority to that obtained from the fish oil (Stammers, 1922).[6]

I am indebted to Messrs. Lever Bros., Ltd., for permission to publish these researches.

THE KAHN TEST IN GENERAL PARALYSIS.

By J. S. DUDGEON, M.D., D.P.H. Belf.,
ASSISTANT MEDICAL OFFICER, COUNTY MENTAL HOSPITAL, WHITTINGHAM, LANCS.

Some months ago my attention was attracted by the Kahn agglutino-precipitation test for syphilis.[1] This test is of very simple technique and has given reliable results in the hands of American workers, Kolmer,[2] Herrold,[3] Grant,[4] and others. Keim and Wile,[5] after comparing this test with the Wassermann in a series of cases of syphilis, classified according to the stage of the disease, came to the conclusion that the Kahn test showed a greater sensitivity in the earlier stages of syphilis, but in the later stages—i.e., tertiary and parasyphilis—it did not appear so sensitive, though comparing very favourably with the Wassermann test. Anderson and Fischer[6] hold that the test has great possibilities as a direct and simple test for the serological diagnosis of syphilis, but recommend that it be more thoroughly worked out before being used as a substitute for the Wassermann.

As the test is one which might easily be carried out in any mental hospital, where it is by no means always convenient to have a Wassermann performed, it would serve to confirm the diagnosis in many a doubtful case of neurosyphilis. Recent work on the treatment of general paralysis would emphasise the importance of an early diagnosis of this condition and, when physical signs are indefinite or confusing, a simple serological test which could be performed on the spot would be of great value.

It was from this point of view that I set out to apply the test to a series of general paralytic bloods on which Wassermann tests were also done. Up to the present the series has been rather limited, chiefly owing to the fact that one phase of syphilis alone has been dealt with, but as Osmond and McClean[7] in this country have published results of the test on a series of 500 cases of general syphilis, it might be of interest to record what has been already done.

The series consisted of 93 bloods from cases of general paralysis, and the technique used was that described by Keim and Wile.[5] An analysis of the results is given here.

(1) 83 cases of G.P.I. giving a positive Wass.
Kahn + + + + 20
+ + + 26
+ + 22
+ 9
± 1
doubtful 1
− 4

(2) 5 cases of G.P.I. giving a doubtful Wass.
Kahn − 5

(3) 5 cases of G.P.I. giving a negative Wass.
Kahn + + + 2
+ + 1
+ 1
± 1

In the non-specific bloods used as controls during these tests one false positive was obtained.

Cerebro-spinal Fluid.—Though this test was intended for blood-serum only, I attempted to apply the technique to spinal fluid. Owing to the weaker precipitating capability of the spinal fluid it was necessary to use 1 c.cm. for each test instead of 0·3 c.cm. as in the serum tests; otherwise no alteration in technique was required. This larger quantity of fluid had, as might be expected, a material effect on the test. A longer incubation period was required before the reading was taken, the precipitates were not so distinct, and did not, even in most strongly positive cases, appear in clumps. Many of the precipitates were of such fine flocculation that they could scarcely be seen without the aid of a hand lens. The heavier precipitates were found to settle at the bottom of the tube, and appeared on gentle shaking as fine white flakes floating about. Twelve hours' incubation before reading was usually found to be sufficient. Up to the present the test has been carried out on 70 spinal fluids, of which 61 were from cases of G.P.I. The following are the results:—

Kahn	+	W.R.	+	48 G.P.I.
,,	−	,,	+	6
,,	+	,,	−	4
,,	doubtful	,,	−	1
,,	−	,,	−	2
,,	−	,,	−	9 non-specific cases.

Summary of Results.

Bloods.—In 93 cases of G.P.I.:

Kahn positive in 83, or 89 per cent.; doubtful in 1.
Wassermann positive in 83, or 89 per cent.; *doubtful in 5.*

Cerebro-spinal Fluid.—In 61 cases of G.P.I.:

Kahn positive in 52, or 5 per cent.; doubtful in 1.
Wassermann positive in 54, or 88 per cent.; doubtful in none.

A large majority of the above cases had received treatment of various forms, malaria, phlogetan, &c., and in some cases this was combined with specific treatment—i.e., salvarsan or tryparsamide. It is impossible to say at this stage what effect the treatment had on the test. Only one untreated case gave a negative Kahn.

The test is simple and rapid, and though it would not appear to be as sensitive as the Wassermann, it is possible that the comparison will be more favourable when a larger number of tests have been performed. It is a good confirmatory test and an excellent routine test for an institution.

I am indebted to Dr. R. M. Clark, medical superintendent, for permission to publish these results, and to Mr. A. H. Fann, chief laboratory assistant, for his valuable help.

Reviews and Notices of Books.

PRACTICE OF MEDICINE.

Edited by FREDERICK TICE, M.D., Professor of Medicine and Clinical Medicine, and Head of the Department of Medicine, University of Illinois, College of Medicine. Ten Volumes and Desk Index, each volume about 600 pp. London: Butterworth and Co.; Hagerston, Maryland: W. F. Prior Co. 1924. £21.

POSSESSORS of this new system of medicine may, by subscribing £1 15*s.* per annum, receive sets of new pages every year, and in this manner it is hoped that the system, which is bound in leather on the loose-leaf principle, may be kept perpetually up to date. The work is entirely American, and is issued under the chief editorship of Dr. Frederick Tice, Professor of Medicine to the University of Illinois. Assisting him are Dr. Julius Friedenwald, of the University of Maryland, Dr. Julius Grinker of the Northwestern University Medical School, and Dr. Luther F. Warren, of the Long Island College Hospital, who are concerned with editing the articles dealing with gastro-enterology, neurology, and general medicine. More than 100 contributors are responsible for the text, their names including those of Walter C. Alvarez, F. H. Baetjer, Lewellys Barker, Nathan E. Brill, Thomas Richardson Brown, B. B. Crohn, Charles Lyman Greene, B. B. Vincent Lyon, C. E. de M. Sajous, and many others familiar to British readers. The first volume contains five chapters devoted to the history of medicine, after which come chapters on "hypersensitiveness," infection and immunity, focal infections, oral sepsis, the analysis of urine and cerebro-spinal fluid, and case-history taking. Following this somewhat disorderly beginning the second volume takes us to a section wherein the tests of functional efficiency of stomach, pancreas, liver, circulatory system, endocrine glands, and kidneys are discussed in detail. Thenceforward the work proceeds on more familiar lines, specific and tropical infections being completed by the middle of the fifth volume, after which diseases of the various organs are dealt with systematically. The eighth volume is devoted to diseases due to intoxications and those of the endocrine glands, whilst Vols. IX. and X. are almost wholly confined to the nervous system.

A general survey of this work leads to an impression that the general editing leaves much to be desired. The extraordinary assortment of subjects in the commencing volume is particularly open to criticism. On what grounds was it decided to lay such stress on allergy as a general factor in pathology? Why is focal infection brought into such vivid prominence, with emphasis on the work of several observers whose interesting publications still await any convincing measure of confirmation? And why is the history of medicine included in a work whose voluminous pages still find no place for diseases of the skin? These things seem to us to betray a distorted perspective which robs the work of much of the value it should possess. The inclusion of detailed descriptions of methods of studying the functional efficiency of various organs is certainly defensible, and it may be noted that the various authors have in some cases devoted considerable space to full descriptions of methods which they afterwards condemn; since their condemnation is reasoned, and full references are given with each article, this section should be of considerable value to those physicians who appreciate the value of help from the laboratories. In principle, however, it is not easy to see why chemical laboratory methods should be quoted in full when equally expert matters such as bacteriological methods are treated quite briefly. No serious attempt is made to deal systematically with the general pathogenic effects of various important organisms such as the pneumococcus, the streptococcus, or the *Bacillus coli communis*, save in a chapter on certain septicæmias. As a result the reader who desires to ascertain, for example, an author's views on infections due to Friedländer's bacillus, may find himself in difficulties. The index gives no help in this respect, nor can any reference to the subject be traced throughout the work except in a chapter on broncho-pneumonia, where it is stated that this disease is sometimes caused by Gram-negative cocci! When we say that this chapter is sandwiched between one on tuberculosis of the genito-urinary system and the one on the septicæmias already alluded to, the reader will realise that the general arrangement may waste the would-be reader's time.

The index is unworthy of the labour spent in compiling these volumes. Each of these is brought to a conclusion by a page which urges the reader to consult the special desk index which is bound separately. This index is itself introduced by a somewhat unctuous page of advice to the reader, who on seeking to make use of the vaunted volume may be gravely embarrassed. For example, no reference is given to cœliac disease; under cirrhosis of the liver we find no mention of progressive lenticular degeneration, and as that disease is described and indexed as "Wilson's disease," a reader unfamiliar with that title would have difficulty in tracing it. Another rare but well-recognised nervous disease, amaurotic family idiocy, is completely omitted from the index, though a sufficient description of it may be found on p. 198 of Vol. X. Other omissions could be cited which are inexcusable in an index which gives heavy-type references to chappara amargoso, cholamin, krameria, speidel salts, pomegranate root, papain, kamala, and other somewhat obscure nostra. The fact that under Milroy's disease this index gives no fewer than 26 references, all referring to the three pages in a single volume where that disease is dealt with, conveys a good idea of how stupidly this part of the work has been performed.

We have devoted much space to discussing the arrangement and indexing of this system of medicine because it is upon these factors that its general utility must largely depend; of that part of the text which deals with the major descriptions of the various diseases, their clinical features, diagnosis, and treatment we have far more pleasant things to say. Many of the articles are excellent. Special tribute is due to Dr. Herman O. Mosenthal for his excellent treatise on diabetes mellitus; and the thorough study of hepatic diseases by Drs. John Ferguson and W. E. Ferguson, and the chief editor's article on pericarditis are admirable. Most of the articles are followed by a bibliography, which even when incomplete is a valuable feature. If the scheme of issuing new pages yearly is carried out with thoroughness, and if proper care is given to the revision of the index, the publication of this ambitious work will have been amply justified, for a full index will meet many of the difficulties in locating information.

THE LEUCOCYTE IN HEALTH AND DISEASE.

By C. J. BOND, C.M.G., F.R.C.S., Fellow of University College, London; Hon. Consulting Surgeon to the Leicester Royal Infirmary; Member of the Cancer Committee, Ministry of Health. London: H. K. Lewis and Co., Ltd. 1924. Pp. 83. 12*s.* 6*d.*

THE author records the results of a number of experiments upon the reaction of the leucocytes to artificially induced changes in their environment. Many of these observations are of interest, as, for instance, the author's clear demonstration of the return of exuded leucocytes into the granulation tissue of a wound surface. Dr. Bond apparently believes that some change in the activity of these cells is brought about by their sojourn in the "liquor puris." On the basis of certain other experiments with incubated blood-clot he claims to be able to render the polymorphs actively phagocytic of red cells, both homologous and heterologous, and this leads him to the conclusion that substances toxic to leucocytes, when present in excess, may in higher dilutions act as opsonins. In the absence of evidence in the shape of protocols, either of experiments or controls, it is impossible to judge of the validity of these conclusions. Of many of the other observations it is difficult to understand the purpose, a difficulty which is enhanced by the author's somewhat inconsecutive and disjointed manner of presenting his facts. It is an index to the highly specialised nature of his researches that of the 33 references given 14 are to Dr. Bond's own works. The book concludes with 48 half-page microphotographs showing leucocytes, mostly in obviously indifferent health as the result of the author's attentions.

COLLECTED PAPERS.

Collected Papers, Physiological Laboratory, King's College, London. No. XXVII. Edited by W. D. HALLIBURTON, M.D., LL.D., F.R.C.P., F.R.S. 1923–1924.

THE present collection of papers will be the last to appear from the Physiological Laboratories of King's College Hospital under the editorship of Prof. Halliburton. That it need represent the editor's actual farewell to physiology there is fortunately no reason to anticipate. Of the 24 papers dealing with original research comprised in the collection, only two—one on the Appendages of the Brain, and a second short note on the Formation of a Reversible Clot by the Action of Pancreatic Juice on Milk—are from his own pen, but all bear the marks of his inspiration. The papers fall into several groups, of which the largest are those constituted by the publications of C. A. da Fano, on histological subjects, and by Dr. J. W. Pickering in collaboration with other members of the laboratory staff, on various points in connexion with the coagulation of the blood. Of Dr. da Fano's papers some deal with the Golgi apparatus of the cell, some with the histology of epidemic encephalitis with particular reference to the "minute" bodies first described by this observer, and some with the histological changes to be observed in the central and sympathetic nervous systems in the "deficiency" diseases. Dr. Pickering has brought to light many points of interest in connexion with the coagulation of the blood. Among other things he has been able to demonstrate that the anti-coagulant action of peptone on intravenous injection cannot be due, as in the view of Howell, to the production of antithrombin by the liver, for it occurs even when that organ is shut out of the circulation. He believes that neither "thrombin" nor "antithrombin" has any existence as an entity, and that coagulation of the blood depends upon the disturbance of a system formed by a protective colloid united to a fibrinogen-prothrombin complex. Dr. J. A. Hewitt, who also writes as one of Dr. Pickering's collaborators, contributes two papers dealing with the metabolism of the carbohydrates—one a destructive criticism of recent work on the relationship of the production of γ from α and β glucose to diabetes, and one on the absorption of various sugars from the gut. Dr. J. A. Shaw-Mackenzie has papers upon his serum reaction for the diagnosis of carcinoma and upon the treatment of inoperable carcinoma by the intravenous injection of sodium oleate.

BIOCHEMISTRY.

Monographs of Biochemistry. Edited by Prof. R. H. A. PLIMMER and Prof. F. G. HOPKINS. *The Simple Carbohydrates and the Glucosides.* Fourth edition. By E. FRANKLAND ARMSTRONG, D.Sc., Ph.D., F.R.S., F.I.C., Fellow of the City and Guilds of London Institute. London: Longmans, Green and Co. 1924. Pp. 293. 16*s.*

IN the past Germany has been regarded as the home of specialised scientific publications. Thus the *Biochemisches Handlexikon* and the *Physiologische Arbeitsmethoden*, edited by Prof. Abderhalden, have become world-famous as collections of articles by specialists. We should not be going too far, perhaps, to state that these German publications have only two serious rivals—namely, the *American Journal of Physiological Reviews* and the "Monographs of Biochemistry." The latter, under the general editorship of Prof. Plimmer and Prof. Hopkins, have earned a well-deserved popularity in this country, and many of the monographs have run to several editions. The volume under consideration has reached the fourth edition and has been greatly enlarged. It contains a masterly summary of the present state of knowledge on the simple carbohydrates. An account of the recent work of Irvine and his co-workers on the constitution of the polysaccharides has been included; the chapter on the relations between configuration and biological action has been rewritten, and special, but not perhaps sufficiently detailed, reference is made to insulin. A very fine bibliography is added.

We congratulate Prof. Armstrong on the new edition, and strongly recommend it to the study of biochemists.

Practical Biochemistry. Second edition. By W. A. OSBORNE and W. J. YOUNG. Melbourne: W. Ramsay. 1924. Pp. 151. 12*s.* 6*d.*

THE elementary class in practical biochemistry for medical students always presents difficulties to the teacher. In this country the class is composed of two types of men: candidates for university degrees with a certain amount of training in organic chemistry, and students for examination of the Conjoint Board by whom very little knowledge of the subject has been acquired. The former class treat the elementary biochemical tests with contempt, since they have performed the majority of them before, whilst the latter are bewildered by even the most simple organic problems. The existing English books on practical work are of very little assistance in overcoming these difficulties, since they are either too chemical or contain soul-destroying experiments with bread, butter, and milk.

The authors of the present volume are to be congratulated in that they have balanced pure and bio-chemistry very evenly, with the result that the reading and experimental matter are of interest to all types of students. The biochemical significance of all the reactions is emphasised, and futile experiments are not described. The section dealing with carbohydrates is admirable; for example, the explanation of the butylene oxide formula for glucose, as here set out, must lose its terror, even for the most elementary student. It is unfortunate that no clinical blood estimations are included, but we may expect this in the promised companion volume on advanced biochemistry.

HYGIENE AND PUBLIC HEALTH.

Fifth edition. By BIRENDRANATH GHOSH, F.R.F.P.S. London: Simpkin, Marshall, Hamilton, Kent and Co., Ltd.; Calcutta: Hilton and Co. 1924. Pp. 586. 9*s.* 6*d.*

THE fifth edition of this concisely written but comprehensive text-book will be welcomed by students of sanitation in India and the tropics. Every chapter has been carefully revised, and it has been found necessary to increase the size of the book by 79 pages. The experience of the war has altered many of our ideas on the subject of the purification of water, and the chlorination of water is now dealt with in some detail. Many of the lessons learnt during the war as to the disposal of refuse, the incineration of night-soil, and the use of improved types of latrines have also been drawn upon. In the chapter on the disposal of sewage the activated sludge process is dealt with. We note, however, that the blowing-in of air is described as a necessary feature of this new process, whereas experience in Sheffield and other places has shown that the simpler and less expensive plan of aerating the sewage by means of paddle-wheels gives equally good results. In the chapter on food, vitamins are less fully treated than is usual nowadays. Little attention is given to the use of dried milk. The opinion of most public health workers in the tropics is that dried milk especially prepared and packed for the tropics is almost an ideal way of meeting the many difficulties involved in securing a satisfactory milk-supply in hot countries.

The smoke nuisance receives little or no attention; we believe that some attempt has been made by the responsible authorities to tackle the factory smoke nuisance in Calcutta and other parts of India. The chapters on vital statistics and maternity and child welfare indicate the immensity of the problem. For example, the average infantile mortality-rate for Calcutta during recent years has been well over 300 per 1000, and about 25,000 to 30,000 mothers in Bengal die every year from causes connected with child-bearing. The chapters on the transmission of diseases by insects and on animal parasites are especially good. A useful section on village sanitation and the sanitation of fairs and religious festivals conclude the book. There are many new illustrations in this edition.

HOME SEWAGE DISPOSAL.

By W. A. HARDENBERGH, Sanitary Engineer and Director of Rural Sanitation, Jefferson County Board of Health, Alabama. London: J. B. Lippincott Company. 1924. Pp. 274. 16*s*.

THIS book fulfils its object in supplying reliable data for health officers and sanitary engineers engaged in solving sewage disposal problems for single homes, small communities, and institutions, and at the same time lays down the principles underlying such problems. The early chapters show the extent of the difficulties encountered in the U.S.A. The author estimates that only 40 per cent. of the population, practically all living in cities, are provided with sewers, and that to the remainder, numbering some 65 millions, the lessons of this book apply. He goes on to show that wherever, as the result of a survey, sanitary privies have been installed in place of unsanitary, a great reduction in the prevalence of typhoid fever has followed. The importance of a sanitary disposal of the body wastes in the prevention of diarrhœa, dysentery, and hook-worm disease (from which disease two millions of the U.S.A. population are said to be suffering) is also emphasised. Details are given of various types of closets and types of septic tank treatment which have proved satisfactory in the U.S.A. The essentials laid down for any method are that it must prevent: (1) the access of flies or animals to the excreta; (2) the scattering of excreta so as to cause soil pollution; (3) the pollution of drinking water or ground water. The English reader may be surprised to find no mention of earth closets. There is certainly difficulty in inducing a rural population to take the trouble required for the proper management of earth closets, but, when this inertia can be overcome, the earth closet, in the opinion of most medical officers of health confronted with the problem in this country, is the best solution. It may be that the prevalence of hook-worm disease renders the earth closet unsuitable for use in America.

DR. PORTEOUS.

By ARTHUR BREBNER. London: A. M. Philpot, Ltd. 1924. Pp. 260. 7*s*. 6*d*.

THIS book is a thoroughly well written account of the life of a general practitioner before the passage of the Insurance Act, and, as questions concerning the vast medical side of this legislation are always with us, and just now bid fair to be brought to the political front, it deserves close perusal for other reasons than its merits as a story. Those merits, it may be said, are high, for it is a well-written and well-observed study of the doctor's life at the end of the last and the beginning of this century. The episodes are, no doubt, arranged for purposes of composition and would not necessarily occur in the lives of many practitioners, or in the same circumstances or in the same order, but as episodes they are illustrative and often poignant.

Certain lines of quotation, placed on the title-page, explain why the hero is found at the end of the book to have deserted the calling of medicine: they are, "let every man be artist of his days, and carve into his life his own caprice." This motto dictates a transfer of Dr. Porteous's energies from general medical practice into the pursuit of art, where his career is triumphant but hardly so close to the facts of life as are his experiences as medical student, assistant, and general practitioner. Indeed, his history as an artist cannot often have been paralleled, and medical men who employ their leisure in painting need not think that their talents can usually be put to such fruitful use. Certainly Dr. Porteous conducted his art education in an effective manner, for during his career as a student he found time to sketch, to copy, to study masterpieces in galleries, to secure models among the porters at the hospital, and to cope with the theories of perspective. By chance he made some water-colour drawings to illustrate a text-book of dermatology by one of his chiefs, and as events turned out, this was a critical action in his life, for when, after many bitter experiences, failure as a medical practitioner seemed to stare him in the face a substantial cheque for these drawings arrived, and, further, the eminent dermatologist, who had been his teacher, put him into touch with an amazing art agent who gave large cheques for pictures on their merits without regard to their market value or their signatures. This gentleman saw one of Dr. Porteous's canvasses, immediately gave him £900 for it, and organised an exhibition on the opening of which the critics confirmed the great merit of the work. At which point the book ends in the distinct promise that the hero will carry all before him in the world of art and live happy and prosperous in the companionship of the devoted wife, who had supported him in his troubles.

Dr. Brebner, who died some ten years ago, had already two successful novels to his name when he wrote this posthumous work.

PICKETT-THOMSON RESEARCH LABORATORY.

Annals of the Pickett-Thomson Research Laboratory. Vol. I., No. 1., July, 1924. Issued from St. Paul's Hospital, London, W.C. Pp. 216. 25*s*.

THIS handsome volume is prefaced by photographs of Sir Ronald Ross and Mr. Pickett, and three views of the interior of the laboratory, which appears to be a very pleasant and well-equipped building. The major part of the Annals consists of three papers by Dr. David Thomson, entitled Researches on the Virus of Variola-Vaccinia, Researches on the Etiology of Measles, and Researches on the Etiology of Scarlet Fever, which occupy about nine-tenths of the volume. These articles are not reprints of papers published elsewhere, but are rather specially written essays. It should be mentioned at once that the researches chronicled are mainly those of workers outside these laboratories, which occupy some 123 pages whilst those of the author, excluding illustrations, only occupy 27 pages, a certain proportion of which is given up to discussions and conclusions. A good deal of Dr. Thomson's personal investigations are concerned with attempts to grow the viruses of the exanthemata in a large variety of media and in tissue cultures. The results in the first case are mainly negative, and in the second are uncertain and inconclusive. Thus, whilst the review of literature is sound and full, and whilst this portion of the volume may be of assistance to those anxious to obtain a résumé of current and past ideas on the subject covered, the amount of original work is relatively insignificant. The conclusions arrived at, briefly summarised, are that the Guarnieri bodies of variola are true parasites, and that as regards measles "the suspicious organisms so far which deserve further investigation are the diplococcus of Tunnicliffe, the streptococci, influenzoid bacilli, and the spirochæte of Salimbeni." The streptococcus is favourably regarded as the causal agent in scarlet fever. The papers are abundantly illustrated by some excellent photographs and coloured plates. Other minor papers bear upon the value of "detoxicated" vaccines in the complications of scarlet fever and in the tuberculin test in cattle, as well as upon experiments on the various methods of detoxication; there is also a description of certain cultural characters of organisms of the meningococcus, gonococcus, and catarrhalis groups, and the distinctive appearances of types and strains which, following Atkin, are utilised for their identification and grouping. The last paper, a clinical one in the main, contains an interesting description of cases of gas poisoning resulting from the breaking down of ammunition in the factory of F. N. Pickett et fils. This comes with something of a shock in reviving almost forgotten memories of matters which were so vividly in the forefront of our preoccupations some eight or nine years ago.

It is not easy to understand quite why the present volume has been written. If it is to be taken as a practical attempt to contribute to our knowledge of disease, as the title of the various papers suggests, it must be said that from the point of view of the laboratory worker it does not succeed in this aim.

MEDICAL INSURANCE PRACTICE.
Second edition. By R. W. HARRIS and LEONARD SHOETEN SACK. London: The Scientific Press, Ltd. 1924. Pp. 347. 7*s.* 6*d.*

A SECOND and revised edition of this useful little ook has appeared within two years of the first. It described by the authors, one of whom was formerly ssistant secretary in the Ministry of Health, and the ther is a barrister-at-law, as a work of reference to he medical benefit provisions of the National Health nsurance Acts. The revised edition incorporates the mendments effected by the Regulations of 1924, an sterisk being placed against new or amended paragraphs in order to call the reader's attention to points n which he should refresh his memory. We have already commended this book as indispensable to the practitioner who wishes to give the best service to his insurance patients with the minimum of risk and inconvenience to himself, and we do so again.

JOURNALS.

BRITISH JOURNAL OF OPHTHALMOLOGY, August, 1924.—F. A. Williamson-Noble describes an apparatus for performing a retinoscopy on a patient with undilated pupil. The apparatus is fixed, and the determination of the shadow movement is effected not by the tilting of the mirror, but by the movement by the observer of his own head.—C. H. Usher contributes a note on the Dog's Tapetum in early life. The tapetum is the structure that causes the green or yellow reflex that is apparent on illuminating the fundus of many animals. Usher by repeated examination has found that it is absent in young puppies up to about the seventh week of life, and that when it is first seen the appearance differs markedly from that seen in the adult animal.—G. F. Rochat and W. Mulder contribute a clinically important paper on Progressive Atrophy of the Iris with Formation of Holes and Glaucoma. It has generally been thought that atrophy of the iris is a condition secondary to disease of the eye, either glaucoma or cyclitis. A few cases, however, have been described in which atrophy and formation of holes in the iris have existed without any apparent cause. The authors describe a case in which the condition was well marked and in which at first the eye was otherwise normal in every respect. Some years later, however, it became blind from glaucoma. In this case, therefore, the atrophy of the iris appears to have been the primary disease.—H. J. Flieringa describes a case of uniocular paralysis of accommodation in a girl of 10 occurring after an affection of the throat which was presumably diphtheritic and clearing up in the ordinary way. A one-sided case of this sort is a rarity.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following table gives some of the principal health statistics of seven boroughs during 1923:—

Name of borough.	Estimated mid-year population.	Birth-rate.	Death-rates per 1000 of the population.				Death-rates per 1000 births.		
			All causes.	Tuberculosis.	Cancer.	Resp. diseases with influenza.	Neonatal mortality.	Infant mortality.	Maternal mort. from childbirth.
Paisley	86,027	23·5	11·5	1·2	1·3	1·3	32	66	6·5
Cambridge ..	59,130	14·8	10·5	0·9	1·6	1·5	25	48	1·1
Nuneaton ..	44·030	22·6	9·4	0·9	0·8	1·9	40	75	3·0
Colchester ..	43,002	18·6	9·7	0·8	1·3	1·4	25	42	3·6
Llanelly	38,300	23·2	10·7	1·6	0·8	1·4	31	70	1·1
Shrewsbury ..	31,600	19·8	12·7	1·0	1·3	2·9	25	62	3·2
Wrexham ..	19,420	18·8	12·9	1·4	1·4	2·2	27	79	2·7

Paisley.

Dr. G. V. T. McMichael includes in his report a drawing of the elevation, and also the plans, of the Central Medical Institute for the mothers and children of Paisley, presented to the town by Miss Russell. of Muirfield. The elevation shows a handsome building occupying a corner site. On the ground floor are the tuberculosis department and the maternity and child welfare department. On the first floor are the minor ailment clinic and the special treatment clinic for diseases of the eye, ear, nose, throat, &c., also the main office of the school medical department. On the second floor are the dental clinic, the orthopædic department, and an X ray department. The plans indicate a building excellently equipped for its purpose. Dr. McMichael, in discussing the housing problem, suggests that it will never be solved until it is lifted right out of the domain of party politics, and a national policy formulated by experts agreed on by all parties. No one, he says, can honestly be satisfied with the present environment of the working classes, especially in our large industrial towns.

Paisley has its special difficulties, as we are told in another part of the report that 69 per cent. of the houses are of one or two apartments. A very satisfactory arrangement has now been made by which all cases of small-pox in Renfrewshire are to be accommodated in the West Renfrewshire small-pox hospital. This arrangement makes the Paisley small-pox hospital permanently available as a clearing house for all cases of tuberculosis requiring institutional treatment. Dr. McMichael is well satisfied with the action of the local authority in 1922 in making all forms of pneumonia notifiable. This has enabled the department to offer hospital treatment to all the severe cases of measles and whooping-cough. A further need is convalescent home treatment for these two diseases. An unusual occurrence mentioned in the report is an outbreak of dysentery. Six members of one household were attacked, the infective organism being the Flexner (Z) bacillus. The first case, a boy of 7, died within 24 hours. At first food poisoning was suspected. The other five cases recovered. Inquiry showed that the father, an ex-Service man, had suffered from dysentery while in the army and had had recurrent attacks of diarrhœa ever since his discharge.

Antenatal work makes progress. During 1923, 404 expectant mothers attended the antenatal clinic, whilst the total births in the year numbered 2020. Dr. McMichael would like to see the Barshaw Maternity dried milk especially prepared and packed for the tropics is almost an ideal way of meeting the many difficulties involved in securing a satisfactory milk-supply in hot countries.

The smoke nuisance receives little or no attention; we believe that some attempt has been made by the responsible authorities to tackle the factory smoke nuisance in Calcutta and other parts of India. The chapters on vital statistics and maternity and child welfare indicate the immensity of the problem. For example, the average infantile mortality-rate for Calcutta during recent years has been well over 300 per 1000, and about 25,000 to 30,000 mothers in Bengal die every year from causes connected with child-bearing. The chapters on the transmission of diseases by insects and on animal parasites are especially good. A useful section on village sanitation and the sanitation of fairs and religious festivals conclude the book. There are many new illustrations in this edition.

HOME SEWAGE DISPOSAL.

By W. A. Hardenbergh, Sanitary Engineer and Director of Rural Sanitation, Jefferson County Board of Health, Alabama. London: J. B. Lippincott Company. 1924. Pp. 274. 16*s*.

This book fulfils its object in supplying reliable data for health officers and sanitary engineers engaged in solving sewage disposal problems for single homes, small communities, and institutions, and at the same time lays down the principles underlying such problems. The early chapters show the extent of the difficulties encountered in the U.S.A. The author estimates that only 40 per cent. of the population, practically all living in cities, are provided with sewers, and that to the remainder, numbering some 65 millions, the lessons of this book apply. He goes on to show that wherever, as the result of a survey, sanitary privies have been installed in place of unsanitary, a great reduction in the prevalence of typhoid fever has followed. The importance of a sanitary disposal of the body wastes in the prevention of diarrhœa, dysentery, and hook-worm disease (from which disease two millions of the U.S.A. population are said to be suffering) is also emphasised. Details are given of various types of closets and types of septic tank treatment which have proved satisfactory in the U.S.A. The essentials laid down for any method are that it must prevent: (1) the access of flies or animals to the excreta; (2) the scattering of excreta so as to cause soil pollution; (3) the pollution of drinking water or ground water. The English reader may be surprised to find no mention of earth closets. There is certainly difficulty in inducing a rural population to take the trouble required for the proper management of earth closets, but, when this inertia can be overcome, the earth closet, in the opinion of most medical officers of health confronted with the problem in this country, is the best solution. It may be that the prevalence of hook-worm disease renders the earth closet unsuitable for use in America.

DR. PORTEOUS.

By Arthur Brebner. London: A. M. Philpot, Ltd. 1924. Pp. 260. 7*s*. 6*d*.

This book is a thoroughly well written account of the life of a general practitioner before the passage of the Insurance Act, and, as questions concerning the vast medical side of this legislation are always with us, and just now bid fair to be brought to the political front, it deserves close perusal for other reasons than its merits as a story. Those merits, it may be said, are high, for it is a well-written and well-observed study of the doctor's life at the end of the last and the beginning of this century. The episodes are, no doubt, arranged for purposes of composition and would not necessarily occur in the lives of many practitioners, or in the same circumstances or in the same order, but as episodes they are illustrative and often poignant.

Certain lines of quotation, placed on the title-page, explain why the hero is found at the end of the book to have deserted the calling of medicine: they are, "let every man be artist of his days, and carve into his life his own caprice." This motto dictates a transfer of Dr. Porteous's energies from general medical practice into the pursuit of art, where his career is triumphant but hardly so close to the facts of life as are his experiences as medical student, assistant, and general practitioner. Indeed, his history as an artist cannot often have been paralleled, and medical men who employ their leisure in painting need not think that their talents can usually be put to such fruitful use. Certainly Dr. Porteous conducted his art education in an effective manner, for during his career as a student he found time to sketch, to copy, to study masterpieces in galleries, to secure models among the porters at the hospital, and to cope with the theories of perspective. By chance he made some water-colour drawings to illustrate a text-book of dermatology by one of his chiefs, and as events turned out, this was a critical action in his life, for when, after many bitter experiences, failure as a medical practitioner seemed to stare him in the face a substantial cheque for these drawings arrived, and, further, the eminent dermatologist, who had been his teacher, put him into touch with an amazing art agent who gave large cheques for pictures on their merits without regard to their market value or their signatures. This gentleman saw one of Dr. Porteous's canvasses, immediately gave him £900 for it, and organised an exhibition on the opening of which the critics confirmed the great merit of the work. At which point the book ends in the distinct promise that the hero will carry all before him in the world of art and live happy and prosperous in the companionship of the devoted wife, who had supported him in his troubles.

Dr. Brebner, who died some ten years ago, had already two successful novels to his name when he wrote this posthumous work.

PICKETT-THOMSON RESEARCH LABORATORY.

Annals of the Pickett-Thomson Research Laboratory. Vol. I., No. 1., July, 1924. Issued from St. Paul's Hospital, London, W.C. Pp. 216. 25*s*.

This handsome volume is prefaced by photographs of Sir Ronald Ross and Mr. Pickett, and three views of the interior of the laboratory, which appears to be a very pleasant and well-equipped building. The major part of the Annals consists of three papers by Dr. David Thomson, entitled Researches on the Virus of Variola-Vaccinia, Researches on the Etiology of Measles, and Researches on the Etiology of Scarlet Fever, which occupy about nine-tenths of the volume. These articles are not reprints of papers published elsewhere, but are rather specially written essays. It should be mentioned at once that the researches chronicled are mainly those of workers outside these laboratories, which occupy some 123 pages whilst those of the author, excluding illustrations, only occupy 27 pages, a certain proportion of which is given up to discussions and conclusions. A good deal of Dr. Thomson's personal investigations are concerned with attempts to grow the viruses of the exanthemata in a large variety of media and in tissue cultures. The results in the first case are mainly negative, and in the second are uncertain and inconclusive. Thus, whilst the review of literature is sound and full, and whilst this portion of the volume may be of assistance to those anxious to obtain a résumé of current and past ideas on the subject covered, the amount of original work is relatively insignificant. The conclusions arrived at, briefly summarised, are that the Guarnieri bodies of variola are true parasites, and that as regards measles "the suspicious organisms so far which deserve further investigation are the diplococcus of Tunnicliffe, the streptococci, influenzoid bacilli, and the spirochæte of Salimbeni." The streptococcus is favourably regarded as the causal agent in scarlet fever. The these tenants are paying very low rents they will require financial assistance to enable them to occupy the municipal houses. The housing committee also give sympathetic consideration in the allocation of houses to families affected by tuberculosis.

Wrexham.

Dr. T. P. Edwards took up his appointment as medical officer of health on Oct. 1st, 1923. One of the chief events of the year was the removal of the maternity and child welfare centre to new and commodious premises in Grosvenor-road. As a result of the move there has been a considerable increase in the attendances. A maternity hospital is needed, and it is hoped to obtain such by coöperation with the county. The only lying-in accommodation at present available is at the hospital of the Wrexham Board of Guardians. The health visitors' reports emphasise the urgent need for working-class houses and give numerous examples of mothers being confined in overcrowded houses. Out of 375 confinements 114 occurred in apartments. These circumstances make the need for a maternity hospital more urgent. Dr. Edwards says that the houses built at present, whether by private enterprise or under the municipal scheme, are not available for the working classes, and that what is needed is the erection of a large number of houses at a low economic rent. It was feared at one period during the year that the severe epidemic of foot-and-mouth disease would undermine the economic as well as the hygienic standards of the borough. Work at the public abattoir was interfered with and the borough was threatened with a scarcity of milk. A new public abattoir is needed. There is one private slaughter-house in the borough and only 12 of the 50 Wrexham butchers use the present public one, the remainder using slaughter-houses outside the borough. There are six common lodging-houses in Wrexham, and the question of providing a municipal model common lodging-house was considered during the year.

MENTAL HOSPITALS SERVICE.

Staffordshire.

THE annual report of the Staffordshire Mental Hospitals Board for 1923 is the first issued by that recently constituted body. Under an Act passed in 1922, it controls the three mental hospitals of the county, each of which has a newly appointed visiting committee. In spite of this system of central control, the separate reports of the three hospitals here published reveal certain differences in administration. For example, the diet at Burntwood is commended by the Visiting Commissioners as being particularly good, whereas that at Stafford is criticised on the usual ground of monotony. The absence of women members on two of the visiting committees is also the subject of comment. It is evident that certain already long delayed repair and rebuilding schemes are being deferred on grounds of economy. The population of Cheddleton is increasing and has almost reached the capacity limit. Burntwood has actually eight males in excess. At Stafford plans had actually been prepared and an estimate obtained for building separate accommodation for tuberculous cases, but this work is not to be carried out. At Cheddleton the farm buildings were stated in last year's report to be in a thoroughly insanitary condition, but they have not been renovated; the hospital badly needs verandahs for the open-air treatment of tuberculosis and acute confusional cases. It may reasonably be concluded from these facts that a central board not directly and closely acquainted with the needs of any single hospital, but responsible for several, is less likely to be sympathetic to the needs of any one of them than the average committee of management. No better illustration of the fact that "Asylum Reform" is solely a question of municipal finance could possibly be found. Many points of varied interest arise from this report. At Stafford Mental Hospital, of which Dr. B. H. Shaw is medical superintendent, a considerable amount of research is being done, the subjects of the work being sugar tolerance and intestinal bacteriology, with special reference to "a more exact method of identification and classification of the various bacteria present." Particular attention is being paid to organisms capable of producing formaldehyde, the absorption of which is regarded as a possible factor in mental disease. Several cases of dysentery occurred which were traced to a carrier of long standing, who "suddenly became excitable and faulty in her habits, thereby spreading the infection." It is complained that 80 per cent. of patients from a certain union area had been detained first for varying periods in the local Poor-law institution, thereby delaying effective treatment, whereas the total of such cases for other districts was only 17 per cent. A vacuum cleaning plant is being installed, no doubt as a sequel to the work done in this hospital in the past in investigating dust infection. The death-rate is the lowest ever recorded here (6·23 per cent.). Burntwood, which is under the medical direction of Dr. J. B. Spence, is building a cinema and a clinical laboratory. A women's "club ward," providing various amenities for well-behaved patients, such as already exists on the male side, is under consideration. Cheddleton is in danger of overcrowding. It is pointed out that a whole block is occupied by idiots and low-grade imbeciles (40 girls and 41 boys), whose removal to a more suitable institution would provide the necessary space. Great progress has, however, been made in training these cases, thanks to the enthusiasm of two sisters who were first sent to a colony for mental defectives to learn their methods. Dr. W. F. Menzies, the medical superintendent, has further hopes in relation to these cases; if arrangements can be made between his department and a newly established orthopædic centre at Leek, he hopes that some of these children with congenital deformities may be trained to walk, and it is believed that "the nerve energy required for walking actually develops some of the latent areas in the brain, thus enlarging their experience of things outside themselves and leading to further intellectual progress." There are four cases in the hospital whose mental disorder is the sequela of lethargic encephalitis: Dr. Menzies's description of this group is probably the first of its kind to appear in a mental hospital report. Trouble with nurses continues, members of the female staff frequently breaking their contracts. The situation continues to be relieved somewhat by the presence of "Danish fully trained nurses for whom the Danish National Council secures one year's study leave for training here"; it has, therefore, been possible from time to time to enforce the rule of calling for the resignation of those who make no attempt to qualify for the technical examinations, or who fail twice in either the preliminary or final." This hospital has no dispenser, and the nearest X ray plant is at Stoke-on-Trent. Dr. Menzies points out that, apart from the value of radiology in studying gastro-intestinal function, "one hardly likes to be without such facilities even as a precaution, for the courts now generally hold that a medical man who omits to have an injury in a patient X rayed is guilty of malpraxis."

West Sussex.

The report of the West Sussex County Mental Hospital, Chichester, for 1923 records an increase in the number of patients, particularly on the female side, where further accommodation is an almost immediate necessity. This could be obtained by evacuating a ward used at present as sleeping quarters for nurses, which would necessitate building a separate nurses' home. It is pointed out that such homes are coming to be regarded as "absolute necessities" in large mental hospitals, and the amenities afforded by them are calculated to attract and retain in the service a better class of nurse. The Visiting Commissioner, while commenting favourably on the patients'

Hospital more fully used, and states that the accommodation there is ample for all serious complications of pregnancy, for abnormal cases of labour, and for necessitous cases. The work of the dental clinic grows. All cases of ophthalmia neonatorum are referred to the Eye Infirmary, and no impairment of sight has resulted from this disease during the past five years. The V.D. clinic opened in October, 1922, is working successfully, and patients are ready and anxious to take advantage of the local facilities for treatment.

Cambridge.

Dr. Andrew J. Laird gives details of the working of the dental clinic for expectant and nursing mothers, and children under 5. Sixty-two mothers took advantage of the treatment offered. The number of extractions was 435, the number of fillings 26, and the number of dentures supplied 28. 117 children under school age were inspected and enrolled in the dental scheme—that is to say, these children will be examined quarterly, and, if necessary, treated, to prevent the incidence of dental disease. Fourteen of these children between the ages of 4 and 5 had 223 sound teeth, 48 decayed saveable teeth, and 8 decayed unsaveable teeth. Dr. Laird reports at length on the housing question. A memorandum of January, 1923, deals with 263 houses, the rents of which vary from 2*s.* to 6*s.* per week. Fully 150 of these would in normal times be dealt with by closing orders. Dr. Laird goes on to say that the urgent requirement of the moment is a smaller and cheaper class of house. He suggests that houses containing two bedrooms with living room and scullery built in terrace form without bathrooms would be desirable. In a memorandum dated November, 1923, he gives information with regard to pre-war modern cottages. These cottages are more than 12 to the acre, the front door opens direct into the front room and there is no bathroom or bath. The area of these houses comes within the standard which entitles them to a subsidy under the Housing Act, 1923. Dr. Laird suggests that these designs, modified to include a food larder and bathroom, might meet the case. A third memorandum dated Nov. 30th, 1923, gives a list of the worst cases of overcrowding in Cambridge, some of them being extremely bad. Proceedings were taken in respect of a milk sample 13 per cent. deficient in fat. The case was dismissed following the judgment given in Hunt *v.* Richardson. In consequence the Cambridge borough council passed a resolution urging the Government to introduce legislation to prevent the sale of milk containing less than 3 per cent. of fat.

Nuneaton.

Dr. K. E. Tapper reports that the percentage of unemployed in Nuneaton has been a low one, and that additional employment has been provided by extension of various factories. The Census figures show that 5756 males are employed in mining and quarrying. The housing shortage still remains acute, though the past year has seen an increase in private enterprise. A hundred dwelling houses a year are needed to meet the growth of the population. During 1923, 89 houses were erected. Dr. Tapper states that the method of the collection of refuse needs improvement. Dust-bins are being substituted for ashpits, and the privies in the sewered areas are being gradually abolished. An extension of the sewers is also needed.

Colchester.

Dr. W. F. Corfield says that the proper housing of the people still causes a good deal of anxiety. A larger number of repairs have been insisted upon than in recent years, but the schedule shows that there are 21 houses quite irreparable, the demolition of which will be recommended as soon as it is possible. Dr. Corfield refers to 1923 as "the amazing year" from a health point of view, and mentions that the mortality of illegitimate infants was only 27·7, there being 36 illegitimate births and only one death of an illegitimate infant. Dr. Corfield regrets that the infant clinic does not seem to appeal to the poorest and most necessitous mothers who need its assistance most. He thinks such mothers do not like meeting mothers better off than themselves who will criticise the poor clothing of their babies. The amount of dried milk sold has increased and the amount given away has decreased. Dr. Corfield thinks the free milk has been of immense benefit. One case of concealment of income in order to obtain free milk occurred during the year. A return recently obtained for another purpose has made it possible to check the statements as to income made by applicants, and it was found that all statements of income given in, excepting the one referred to above, were correct.

Llanelly.

Dr. Laurence W. Pole states that special attention during 1923 has been given to the milk-supply of the town. The borough council decided to refuse registration of premises which retailed goods of a general nature. The Milk and Dairies Act of 1922 has also been used for the improvement of dairy-farms and cowsheds. Dr. Pole would like to have a more exact definition of what is meant by the distribution of milk "likely to endanger the public health." Antenatal work is making but slow progress, but Dr. Pole thinks real progress would result through the coöperation of the midwives if the town council were made the supervising authority under the Act.

In the school report it is mentioned that four classes for dull and backward children were formed during the year and have worked with very satisfactory results. Dental treatment is to be begun, as the education committee have approved the appointment of a whole-time dental surgeon. A very satisfactory report is submitted by the instructor in physical training. A class for teachers aroused much interest and only a third of the applicants could be accommodated. A physical training display was organised in June, in which 3000 children took part. About £200 were raised and this sum was utilised to send 100 boys to a holiday camp during August. For the purpose of the camp about 10 acres of land close to a good beach were obtained on the Gower coast some 20 miles from Llanelly. The description given of the camp indicates that the experiment was a great success.

Shrewsbury.

Dr. H. Gordon Smith mentions among noteworthy improvements during the year the provision of a plant for filtering, aerating, re-heating, and circulating the water in the swimming baths. Since the installation of Bell's pressure filters for the Severn water in 1900, Dr. Smith says that enteric fever has been almost unknown. These filters were renovated during 1923. In November the new Shrewsbury and Atcham joint isolation hospital was opened with accommodation for 26 patients. Dr. Smith refers to the prevalence of goitre in Shropshire, but thinks that the estimate that one in five of the female population of Shrewsbury are affected is an exaggeration. He further points out that the disease can readily be prevented by the use of a suitable form of iodine, as has been successfully done in America. An antenatal clinic, conducted by an experienced local practitioner, will be opened during the present year. Severe epidemics of measles and whooping-cough during the year made it necessary to increase the amount of free milk distributed at the centre. Owing to foot-and-mouth disease the number of animals slaughtered at the public abattoir shows a decrease. A vat has been installed for sterilising and rendering down condemned meat, to take the place of the former unsatisfactory procedure of drenching with disinfectant and delivering to a farmer for burial. Municipal housing schemes make slow but steady progress, and an impetus has been given to private enterprise during the last few months. Unfit houses are only patched, but the council intends to close a few of the worst and to offer the tenants accommodation in the municipal houses. As many of these tenants are paying very low rents they will require financial assistance to enable them to occupy the municipal houses. The housing committee also give sympathetic consideration in the allocation of houses to families affected by tuberculosis.

Wrexham.

Dr. T. P. Edwards took up his appointment as medical officer of health on Oct. 1st, 1923. One of the chief events of the year was the removal of the maternity and child welfare centre to new and commodious premises in Grosvenor-road. As a result of the move there has been a considerable increase in the attendances. A maternity hospital is needed, and it is hoped to obtain such by coöperation with the county. The only lying-in accommodation at present available is at the hospital of the Wrexham Board of Guardians. The health visitors' reports emphasise the urgent need for working-class houses and give numerous examples of mothers being confined in overcrowded houses. Out of 375 confinements 114 occurred in apartments. These circumstances make the need for a maternity hospital more urgent. Dr. Edwards says that the houses built at present, whether by private enterprise or under the municipal scheme, are not available for the working classes, and that what is needed is the erection of a large number of houses at a low economic rent. It was feared at one period during the year that the severe epidemic of foot-and-mouth disease would undermine the economic as well as the hygienic standards of the borough. Work at the public abattoir was interfered with and the borough was threatened with a scarcity of milk. A new public abattoir is needed. There is one private slaughter-house in the borough and only 12 of the 50 Wrexham butchers use the present public one, the remainder using slaughter-houses outside the borough. There are six common lodging-houses in Wrexham, and the question of providing a municipal model common lodging-house was considered during the year.

MENTAL HOSPITALS SERVICE.

Staffordshire.

THE annual report of the Staffordshire Mental Hospitals Board for 1923 is the first issued by that recently constituted body. Under an Act passed in 1922, it controls the three mental hospitals of the county, each of which has a newly appointed visiting committee. In spite of this system of central control, the separate reports of the three hospitals here published reveal certain differences in administration. For example, the diet at Burntwood is commended by the Visiting Commissioners as being particularly good, whereas that at Stafford is criticised on the usual ground of monotony. The absence of women members on two of the visiting committees is also the subject of comment. It is evident that certain already long delayed repair and rebuilding schemes are being deferred on grounds of economy. The population of Cheddleton is increasing and has almost reached the capacity limit. Burntwood has actually eight males in excess. At Stafford plans had actually been prepared and an estimate obtained for building separate accommodation for tuberculous cases, but this work is not to be carried out. At Cheddleton the farm buildings were stated in last year's report to be in a thoroughly insanitary condition, but they have not been renovated; the hospital badly needs verandahs for the open-air treatment of tuberculosis and acute confusional cases. It may reasonably be concluded from these facts that a central board not directly and closely acquainted with the needs of any single hospital, but responsible for several, is less likely to be sympathetic to the needs of any one of them than the average committee of management. No better illustration of the fact that "Asylum Reform" is solely a question of municipal finance could possibly be found. Many points of varied interest arise from this report. At Stafford Mental Hospital, of which Dr. B. H. Shaw is medical superintendent, a considerable amount of research is being done, the subjects of the work being sugar tolerance and intestinal bacteriology, with special reference to "a more exact method of identification and classification of the various bacteria present." Particular attention is being paid to organisms capable of producing formaldehyde, the absorption of which is regarded as a possible factor in mental disease. Several cases of dysentery occurred which were traced to a carrier of long standing, who "suddenly became excitable and faulty in her habits, thereby spreading the infection." It is complained that 80 per cent. of patients from a certain union area had been detained first for varying periods in the local Poor-law institution, thereby delaying effective treatment, whereas the total of such cases for other districts was only 17 per cent. A vacuum cleaning plant is being installed, no doubt as a sequel to the work done in this hospital in the past in investigating dust infection. The death-rate is the lowest ever recorded here (6·23 per cent.). Burntwood, which is under the medical direction of Dr. J. B. Spence, is building a cinema and a clinical laboratory. A women's "club ward," providing various amenities for well-behaved patients, such as already exists on the male side, is under consideration. Cheddleton is in danger of overcrowding. It is pointed out that a whole block is occupied by idiots and low-grade imbeciles (40 girls and 41 boys), whose removal to a more suitable institution would provide the necessary space. Great progress has, however, been made in training these cases, thanks to the enthusiasm of two sisters who were first sent to a colony for mental defectives to learn their methods. Dr. W. F. Menzies, the medical superintendent, has further hopes in relation to these cases; if arrangements can be made between his department and a newly established orthopædic centre at Leek, he hopes that some of these children with congenital deformities may be trained to walk, and it is believed that "the nerve energy required for walking actually develops some of the latent areas in the brain, thus enlarging their experience of things outside themselves and leading to further intellectual progress." There are four cases in the hospital whose mental disorder is the sequela of lethargic encephalitis: Dr. Menzies's description of this group is probably the first of its kind to appear in a mental hospital report. Trouble with nurses continues, members of the female staff frequently breaking their contracts. The situation continues to be relieved somewhat by the presence of "Danish fully trained nurses for whom the Danish National Council secures one year's study leave for training here"; it has, therefore, been possible from time to time to enforce the rule of calling for the resignation of those who make no attempt to qualify for the technical examinations, or who fail twice in either the preliminary or final." This hospital has no dispenser, and the nearest X ray plant is at Stoke-on-Trent. Dr. Menzies points out that, apart from the value of radiology in studying gastro-intestinal function, "one hardly likes to be without such facilities even as a precaution, for the courts now generally hold that a medical man who omits to have an injury in a patient X rayed is guilty of malpraxis."

West Sussex.

The report of the West Sussex County Mental Hospital, Chichester, for 1923 records an increase in the number of patients, particularly on the female side, where further accommodation is an almost immediate necessity. This could be obtained by evacuating a ward used at present as sleeping quarters for nurses, which would necessitate building a separate nurses' home. It is pointed out that such homes are coming to be regarded as "absolute necessities" in large mental hospitals, and the amenities afforded by them are calculated to attract and retain in the service a better class of nurse. The Visiting Commissioner, while commenting favourably on the patients'

classification, also suggests the provision of an admission hospital, where newly admitted patients could be kept apart from all others. This hospital has a consulting staff of five members for dental, surgical, and other specialised work, and it is implied that an additional resident medical officer will shortly be appointed, part of whose duties will consist of pathological work. There is a well-equipped laboratory which for some years has remained unused. The death-rate during the year reached the remarkably low figure of 4 per cent. An outbreak of influenza affecting 230 patients and members of the staff threw a great strain on the resources of the hospital, but no case ended fatally, and other infectious disease has been rare. Dr. H. A. Kidd, the medical superintendent, discussing the results of treatment, points out that a recovery-rate, based on all the patients admitted—including congenital cases, senile and organic dementias—does not fairly represent these results, which are shown not only in complete recovery but in relief from active symptoms, in return to orderly conduct, and in improved general health. Separate statements are made by the engineer, steward, and farm bailiff on the work of their departments.

Cardiff.

No remarkable developments are recorded by Dr. E. Goodall in the annual report of the City of Cardiff Mental Hospital for 1923. There has been little change in the number of patients under treatment. The policy of staffing male wards with female nurses is being continued, and it is interesting to note that a number of nurses are being instructed in massage. Research by the pathological staff of three members, who receive grants from the Medical Research Council, has been devoted to the same ends as those referred to in last year's report. They include the estimation of total nitrogen, sugar, and chlorides in the blood and cerebro-spinal fluid of cases of epilepsy, sugar-tolerance tests in epilepsy and general paralysis, an investigation of the toxicity of the blood-serum and corpuscles in acute insanity of various kinds, which has included attempts to produce antibodies by animal inoculations, certain radiographic work on the digestive functions (which has been published and reviewed in our columns[1]), and an "investigation of the bacterial content of the alimentary and urinary tracts," of which insufficient particulars are given to judge of its exact nature. The very large amount of biochemical work carried out during the last few years has been devoted to somewhat unpromising ends, and it is to be hoped that the staff of the best equipped research laboratory in any mental hospital in this country will not be discouraged from breaking some entirely fresh ground by the failure of their work hitherto to produce any definite or illuminating conclusions. It is with some surprise that one reads of a sporadic case of dysentery, from which the stools were sent to the County Public Health Laboratory in Cardiff for bacteriological examination, and the blood for agglutination tests to Oxford. Dysentery is not an uncommon disease in mental hospitals, and it might have been supposed that in an institution so well equipped from the laboratory standpoint as this such work could have been done on the premises.

Birmingham.

The annual report of the asylums committee of the city of Birmingham, as in former years, is a singularly complete and illuminating record of the work at Winson Green, under Dr. C. B. Roscrow, and Rubery Hill, under Dr. T. C. Graves. As an example of its thoroughness may be cited the detailed and enlightened analysis of ætiology in regard not only to the new cases admitted, but to those which recovered during the year. A comparison of these two tables yields no very striking contrasts, but it is interesting to observe that "sepsis" was regarded as a contributory cause in no less than 241 admissions, and had been present in 60 cases which recovered. In order more effectively to cope with bodily conditions whose existence may be supposed to retard recovery, there is now a visiting staff including two throat and aural surgeons, and a gynæcologist, in addition to the dental surgeon. Pathological investigations are, of course, carried out at the Hollymoor Research Laboratory, Hollymoor being an annexe of Rubery Hill. The latter is an old building, and at the present rate of admissions will soon require extension; the Visiting Commissioner expresses the hope that when this is undertaken verandahs, clinical rooms, and other amenities may be included in the plans. His only adverse comment of the administration regards the extensive use of condensed milk in the dietary. Not everyone will agree with Dr. Graves, the medical superintendent of Rubery Hill, in the following observations on occupational treatment: "The subject of employment of mentally afflicted patients has been much under discussion of late, and the term occupational therapy has been devised. I would only remark that prior to the onset of their mental breakdown patients have generally been at work. The proper way to regard employment is as a test of physical and mental capacity during convalescence, in a similar way to that adopted in sanatoria for tuberculosis by graduated exercise and work." The absence of a list of the medical staff is unusual and confusing. In the interest of veracity it should be observed that the possession by all the (assistant) medical officers at Rubery Hill of the Diploma in Psychological Medicine is not a "unique circumstance." At least one other English mental hospital, with a staff of four or five members, possesses this distinction.

Monmouthshire.

In the annual report of the Monmouthshire Asylum, Abergavenny, Dr. N. R. Phillips records a considerable increase in the population of this hospital, which, if continued, will necessitate internal re-arrangement. There is a building, Maindiff Court, which at present remains unused, and several purposes have a claim on it; separate accommodation for recent admissions, and the isolation of the tuberculous, of whom there are 31 known cases in the hospital at the present time, are perhaps the most important. Suggestions from this point of view are made in the report of the Visiting Commissioner, who also criticises the diet, certain mortuary and bathroom arrangements, the system of record-keeping, and the facilities for sterilising foul washing. It is therefore somewhat irritating to read in the remarks of the chairman of the committee that the report of His Majesty's Commissioner "was again quite satisfactory." This report also states that 31 cases of dysentery, with three deaths, occurred between August, 1922, and October, 1923, whereas the report of the medical superintendent observes: "The health of the patients generally was good, and, except for a fatal case of enteric fever and a small amount of colitis, there was no epidemic disease." The death-rate was the lowest on record for the hospital, 5·7 per cent., and the recovery-rate is rising; many patients appear to receive parole and leave on trial, but of the latter very few receive money allowances.

SCHOOL MEDICAL SERVICE.

Leeds.

THE Leeds children of subnormal nutrition are kept under strict observation. They are regularly weighed by the school nurse and the results recorded by graphs. Parents are advised as to diet and treatment where necessary, and if a child does not appear to be making sufficiently rapid progress he is presented for examination by the school doctor. Children having free meals are regularly weighed. The parent of every school child in Leeds has been given a leaflet with sensible advice on broad lines as to food and its value. This is evidently necessary. Of the

---

[1] THE LANCET, 1924, i., 859.

39 children examined in the nursery school only one was found to have no defects, the other 38 giving a total of 152 various defects. The necessity for nursery schools in industrial areas is obvious, but this figure is alarming. During the autumn an epidemic of conjunctivitis due to the Koch-Weeks bacillus occurred throughout the schools in the city. Prompt measures were taken, and by the end of the year the number of cases had declined considerably, but the number of attendances for this trouble at the clinic had advanced from 4615 during 1922 to 8707 this year. The Central clinic is now completely housed in one building, with good waiting-room accommodation. The consulting rooms are bright and airy, and the new arrangement will add to the comfort of parents and children as well as to that of the staff. Overcrowding of clinics leads to hasty work, which is bound to depreciate in quality.

An interesting investigation into the incidence of defective vision in the various types of schools is given.

	Per cent.		Per cent.
Elementary schools ..	31·1	Special schools ..	38·2
Secondary schools ..	53·0	Industrial schools	55·1
Day trade schools ..	40·0		

The actual numbers of which the percentage is taken is not given, and therefore no positive deductions can be drawn, but it would be an interesting piece of research to work out the actual incidence of defective vision in these schools and to elucidate the amount of myopia in each. A percentage of 29·9 children was found at routine inspection to require treatment. Dr. Algernon Wear laments the apathy of parents with regard to dental defects. Only 39·1 per cent. of the children with dental disease were dealt with during the year. The report on physical training in Leeds is instructive, and an analysis on broad lines of the graph of school absences given at the end would be most useful.

Dewsbury.

The school medical service in Dewsbury has cost the ratepayers 0·73*d.* in the pound, or 2*s.* 1*d.* per school child. A total of 3929 children were inspected in the schools, while medical and dental consultations altogether amounted to 41,747, not including 4018 visits by nurses to the homes of the children. The average cost of each consultation and inspection, including all necessary treatment, worked out at 5*d.* a head. A special investigation into the question of stammering is being conducted, although so far there does not appear to be any class for treatment of these cases, of whom 24 boys and 13 girls have been examined. Of 1151 children inspected by the school dentist 1002 were referred for treatment, and just over two-thirds of these were actually treated, a considerable increase on last year's figure. Dr. Oscar M. Holden deplores the lack of an open-air school in Dewsbury, which he says is no exception to other industrial towns where the number of undersized men and women at present so obvious would be considerably reduced by facilities for open-air education and healthy living.

Nuneaton.

Dr. K. E. Tapper reports that the five-year-old entrants show a high percentage of defects, and he is endeavouring to bring about a closer coöperation between the school medical service and the maternity and child welfare work in Nuneaton. The school clinic, which is open daily for special inspections, had a total of 5739 attendances made by 1648 children. Chorea, both in the acute and early stages, was prevalent among those attending. There was also a large attendance of dyspeptic cases. At the minor-ailment treatment centre 698 children made altogether 5828 attendances. This clinic is held daily by one of the school nurses, a charge of 6*d.* a week being made. In addition, the school clinic is available for tonsil and adenoid operations, refractions and eye defects, dental and X ray treatment. Chronic ear discharge presents the usual problem, and it is hoped that treatment by ionisation will shortly be available for this condition.

St. Helens.

At the routine medical inspection 28·8 per cent. of children attending elementary schools and 23·8 per cent. attending secondary schools were found suffering from defects requiring treatment. Of elementary school-children 71·5 per cent. and of secondary school-children 59·2 per cent. were treated before the end of the year. Dr. Frank Hauxwell gives an interesting graph showing that a rise or fall in the percentage of the total number of cases treated by the local authority does not always mean an increase or decrease in the total number of cases treated. It is apparent, however, from a close study of the figures given, that the percentage of dental defects treated is falling, and indeed is much smaller than the percentage of medical defects treated. That the annual percentage treated should fall from 60 per cent. in 1920 to 37 per cent. in 1923 is the natural result of the increased number of inspections which have to be carried out. With only one dentist it is impossible to treat more than a certain proportion of the defects found. Dr. Hauxwell attributes the smaller proportion of dental defects treated as compared with medical defects to the apathy of parents and lack of education in this direction, as well as to restricted facilities for treatment. It is obvious that additional dental help is required here.

Lindsey.

Dr. R. Ashleigh Glegg reports that 87 per cent. of the children here require dental treatment, while only 15 per cent. were found to need any other definite treatment. He emphasises the need for further dental help, as at present there is one dentist available for 39,000 children, so that only about 5 per cent. can be treated. Dr. Glegg is anxious to extend the teaching of hygiene in schools and urges that it be given a definite place in the time-table, especially in the upper standards.

Blackburn.

The most important developments during the year have been: (1) The establishment of a residential open-air school for delicate children; (2) the appointment of an orthopædic surgeon, and provision for the after-care of cripples; (3) provision for the retention of enlarged tonsils and adenoids cases in hospital for 48 hours after operation; (4) considerable improvements in the sanitary conditions of many of the schools; (5) extension of health education in schools. Considerable progress has been made in developing a scheme for education in health matters. Topical posters have been exhibited in the schools; a booklet entitled "Health Notes" has been distributed to parents, and 23 health rules have been drawn up and rewards given to children who carry out the greatest number. The treatment for stammering started in August, 1921, was continued. Since the inception of these classes 84 children have been dealt with, and of these 46 had a short revision course. The results are good. Fifty-three speak well and clearly, with no stammer. Fourteen speak with occasional hesitation; nine are improved, and eight made no improvement. In those cases where there was complete failure the result was due, as usual, to indifference on the part of the stammerer and his parents, with a consequent lack of coöperation between the home and the school. Dr. W. Allen Daley reports that over 6000 children were examined during the school year, making, with those who received special inspections and reinspections, a total of 11,544 altogether. Of the code groups 14·6 per cent. were found to require treatment, while of the total number examined 48 per cent. required either treatment or observation.

classification, also suggests the provision of an admission hospital, where newly admitted patients could be kept apart from all others. This hospital has a consulting staff of five members for dental, surgical, and other specialised work, and it is implied that an additional resident medical officer will shortly be appointed, part of whose duties will consist of pathological work. There is a well-equipped laboratory which for some years has remained unused. The death-rate during the year reached the remarkably low figure of 4 per cent. An outbreak of influenza affecting 230 patients and members of the staff threw a great strain on the resources of the hospital, but no case ended fatally, and other infectious disease has been rare. Dr. H. A. Kidd, the medical superintendent, discussing the results of treatment, points out that a recovery-rate, based on all the patients admitted—including congenital cases, senile and organic dementias—does not fairly represent these results, which are shown not only in complete recovery but in relief from active symptoms, in return to orderly conduct, and in improved general health. Separate statements are made by the engineer, steward, and farm bailiff on the work of their departments.

Cardiff.

No remarkable developments are recorded by Dr. E. Goodall in the annual report of the City of Cardiff Mental Hospital for 1923. There has been little change in the number of patients under treatment. The policy of staffing male wards with female nurses is being continued, and it is interesting to note that a number of nurses are being instructed in massage. Research by the pathological staff of three members, who receive grants from the Medical Research Council, has been devoted to the same ends as those referred to in last year's report. They include the estimation of total nitrogen, sugar, and chlorides in the blood and cerebro-spinal fluid of cases of epilepsy, sugar-tolerance tests in epilepsy and general paralysis, an investigation of the toxicity of the blood-serum and corpuscles in acute insanity of various kinds, which has included attempts to produce antibodies by animal inoculations, certain radiographic work on the digestive functions (which has been published and reviewed in our columns[1]), and an "investigation of the bacterial content of the alimentary and urinary tracts," of which insufficient particulars are given to judge of its exact nature. The very large amount of biochemical work carried out during the last few years has been devoted to somewhat unpromising ends, and it is to be hoped that the staff of the best equipped research laboratory in any mental hospital in this country will not be discouraged from breaking some entirely fresh ground by the failure of their work hitherto to produce any definite or illuminating conclusions. It is with some surprise that one reads of a sporadic case of dysentery, from which the stools were sent to the County Public Health Laboratory in Cardiff for bacteriological examination, and the blood for agglutination tests to Oxford. Dysentery is not an uncommon disease in mental hospitals, and it might have been supposed that in an institution so well equipped from the laboratory standpoint as this such work could have been done on the premises.

Birmingham.

The annual report of the asylums committee of the city of Birmingham, as in former years, is a singularly complete and illuminating record of the work at Winson Green, under Dr. C. B. Roscrow, and Rubery Hill, under Dr. T. C. Graves. As an example of its thoroughness may be cited the detailed and enlightened analysis of ætiology in regard not only to the new cases admitted, but to those which recovered during the year. A comparison of these two tables yields no very striking contrasts, but it is interesting to observe that "sepsis" was regarded as a contributory cause in no less than 211 admissions, and had been present in 60 cases which recovered. In order more effectively to cope with bodily conditions whose existence may be supposed to retard recovery, there is now a visiting staff including two throat and aural surgeons, and a gynæcologist, in addition to the dental surgeon. Pathological investigations are, of course, carried out at the Hollymoor Research Laboratory, Hollymoor being an annexe of Rubery Hill. The latter is an old building, and at the present rate of admissions will soon require extension; the Visiting Commissioner expresses the hope that when this is undertaken verandahs, clinical rooms, and other amenities may be included in the plans. His only adverse comment of the administration regards the extensive use of condensed milk in the dietary. Not everyone will agree with Dr. Graves, the medical superintendent of Rubery Hill, in the following observations on occupational treatment: "The subject of employment of mentally afflicted patients has been much under discussion of late, and the term occupational therapy has been devised. I would only remark that prior to the onset of their mental breakdown patients have generally been at work. The proper way to regard employment is as a test of physical and mental capacity during convalescence, in a similar way to that adopted in sanatoria for tuberculosis by graduated exercise and work." The absence of a list of the medical staff is unusual and confusing. In the interest of veracity it should be observed that the possession by all the (assistant) medical officers at Rubery Hill of the Diploma in Psychological Medicine is not a "unique circumstance." At least one other English mental hospital, with a staff of four or five members, possesses this distinction.

Monmouthshire.

In the annual report of the Monmouthshire Asylum, Abergavenny, Dr. N. R. Phillips records a considerable increase in the population of this hospital, which, if continued, will necessitate internal re-arrangement. There is a building, Maindiff Court, which at present remains unused, and several purposes have a claim on it; separate accommodation for recent admissions, and the isolation of the tuberculous, of whom there are 31 known cases in the hospital at the present time, are perhaps the most important. Suggestions from this point of view are made in the report of the Visiting Commissioner, who also criticises the diet, certain mortuary and bathroom arrangements, the system of record-keeping, and the facilities for sterilising foul washing. It is therefore somewhat irritating to read in the remarks of the chairman of the committee that the report of His Majesty's Commissioner "was again quite satisfactory." This report also states that 31 cases of dysentery, with three deaths, occurred between August, 1922, and October, 1923, whereas the report of the medical superintendent observes: "The health of the patients generally was good, and, except for a fatal case of enteric fever and a small amount of colitis, there was no epidemic disease." The death-rate was the lowest on record for the hospital, 5·7 per cent., and the recovery-rate is rising; many patients appear to receive parole and leave on trial, but of the latter very few receive money allowances.

SCHOOL MEDICAL SERVICE.

Leeds.

THE Leeds children of subnormal nutrition are kept under strict observation. They are regularly weighed by the school nurse and the results recorded by graphs. Parents are advised as to diet and treatment where necessary, and if a child does not appear to be making sufficiently rapid progress he is presented for examination by the school doctor. Children having free meals are regularly weighed. The parent of every school child in Leeds has been given a leaflet with sensible advice on broad lines as to food and its value. This is evidently necessary. Of the

---

[1] THE LANCET, 1924, i., 859.

39 children examined in the nursery school only one was found to have no defects, the other 38 giving a total of 152 various defects. The necessity for nursery schools in industrial areas is obvious, but this figure is alarming. During the autumn an epidemic of conjunctivitis due to the Koch-Weeks bacillus occurred throughout the schools in the city. Prompt measures were taken, and by the end of the year the number of cases had declined considerably, but the number of attendances for this trouble at the clinic had advanced from 4615 during 1922 to 8707 this year. The Central clinic is now completely housed in one building, with good waiting-room accommodation. The consulting rooms are bright and airy, and the new arrangement will add to the comfort of parents and children as well as to that of the staff. Overcrowding of clinics leads to hasty work, which is bound to depreciate in quality.

An interesting investigation into the incidence of defective vision in the various types of schools is given.

	Per cent.		Per cent.
Elementary schools ..	31·1	Special schools ..	38·2
Secondary schools ..	53·0	Industrial schools	55·1
Day trade schools ..	40·0		

The actual numbers of which the percentage is taken is not given, and therefore no positive deductions can be drawn, but it would be an interesting piece of research to work out the actual incidence of defective vision in these schools and to elucidate the amount of myopia in each. A percentage of 29·9 children was found at routine inspection to require treatment. Dr. Algernon Wear laments the apathy of parents with regard to dental defects. Only 39·1 per cent. of the children with dental disease were dealt with during the year. The report on physical training in Leeds is instructive, and an analysis on broad lines of the graph of school absences given at the end would be most useful.

Dewsbury.

The school medical service in Dewsbury has cost the ratepayers 0·73*d.* in the pound, or 2*s.* 1*d.* per school child. A total of 3929 children were inspected in the schools, while medical and dental consultations altogether amounted to 41,747, not including 4018 visits by nurses to the homes of the children. The average cost of each consultation and inspection, including all necessary treatment, worked out at 5*d.* a head. A special investigation into the question of stammering is being conducted, although so far there does not appear to be any class for treatment of these cases, of whom 24 boys and 13 girls have been examined. Of 1151 children inspected by the school dentist 1002 were referred for treatment, and just over two-thirds of these were actually treated, a considerable increase on last year's figure. Dr. Oscar M. Holden deplores the lack of an open-air school in Dewsbury, which he says is no exception to other industrial towns where the number of undersized men and women at present so obvious would be considerably reduced by facilities for open-air education and healthy living.

Nuneaton.

Dr. K. E. Tapper reports that the five-year-old entrants show a high percentage of defects, and he is endeavouring to bring about a closer coöperation between the school medical service and the maternity and child welfare work in Nuneaton. The school clinic, which is open daily for special inspections, had a total of 5739 attendances made by 1648 children. Chorea, both in the acute and early stages, was prevalent among those attending. There was also a large attendance of dyspeptic cases. At the minor-ailment treatment centre 698 children made altogether 5828 attendances. This clinic is held daily by one of the school nurses, a charge of 6*d.* a week being made. In addition, the school clinic is available for tonsil and adenoid operations, refractions and eye defects, dental and X ray treatment. Chronic ear discharge presents the usual problem, and it is hoped that treatment by ionisation will shortly be available for this condition.

St. Helens.

At the routine medical inspection 28·8 per cent. of children attending elementary schools and 23·8 per cent. attending secondary schools were found suffering from defects requiring treatment. Of elementary school-children 71·5 per cent. and of secondary school-children 59·2 per cent. were treated before the end of the year. Dr. Frank Hauxwell gives an interesting graph showing that a rise or fall in the percentage of the total number of cases treated by the local authority does not always mean an increase or decrease in the total number of cases treated. It is apparent, however, from a close study of the figures given, that the percentage of dental defects treated is falling, and indeed is much smaller than the percentage of medical defects treated. That the annual percentage treated should fall from 60 per cent. in 1920 to 37 per cent. in 1923 is the natural result of the increased number of inspections which have to be carried out. With only one dentist it is impossible to treat more than a certain proportion of the defects found. Dr. Hauxwell attributes the smaller proportion of dental defects treated as compared with medical defects to the apathy of parents and lack of education in this direction, as well as to restricted facilities for treatment. It is obvious that additional dental help is required here.

Lindsey.

Dr. R. Ashleigh Glegg reports that 87 per cent. of the children here require dental treatment, while only 15 per cent. were found to need any other definite treatment. He emphasises the need for further dental help, as at present there is one dentist available for 39,000 children, so that only about 5 per cent. can be treated. Dr. Glegg is anxious to extend the teaching of hygiene in schools and urges that it be given a definite place in the time-table, especially in the upper standards.

Blackburn.

The most important developments during the year have been: (1) The establishment of a residential open-air school for delicate children; (2) the appointment of an orthopædic surgeon, and provision for the after-care of cripples; (3) provision for the retention of enlarged tonsils and adenoids cases in hospital for 48 hours after operation; (4) considerable improvements in the sanitary conditions of many of the schools; (5) extension of health education in schools. Considerable progress has been made in developing a scheme for education in health matters. Topical posters have been exhibited in the schools; a booklet entitled "Health Notes" has been distributed to parents, and 23 health rules have been drawn up and rewards given to children who carry out the greatest number. The treatment for stammering started in August, 1921, was continued. Since the inception of these classes 84 children have been dealt with, and of these 46 had a short revision course. The results are good. Fifty-three speak well and clearly, with no stammer. Fourteen speak with occasional hesitation; nine are improved, and eight made no improvement. In those cases where there was complete failure the result was due, as usual, to indifference on the part of the stammerer and his parents, with a consequent lack of coöperation between the home and the school. Dr. W. Allen Daley reports that over 6000 children were examined during the school year, making, with those who received special inspections and reinspections, a total of 11,544 altogether. Of the code groups 14·6 per cent. were found to require treatment, while of the total number examined 48 per cent. required either treatment or observation.

classification, also suggests the provision of an admission hospital, where newly admitted patients could be kept apart from all others. This hospital has a consulting staff of five members for dental, surgical, and other specialised work, and it is implied that an additional resident medical officer will shortly be appointed, part of whose duties will consist of pathological work. There is a well-equipped laboratory which for some years has remained unused. The death-rate during the year reached the remarkably low figure of 4 per cent. An outbreak of influenza affecting 230 patients and members of the staff threw a great strain on the resources of the hospital, but no case ended fatally, and other infectious disease has been rare. Dr. H. A. Kidd, the medical superintendent, discussing the results of treatment, points out that a recovery-rate, based on all the patients admitted—including congenital cases, senile and organic dementias—does not fairly represent these results, which are shown not only in complete recovery but in relief from active symptoms, in return to orderly conduct, and in improved general health. Separate statements are made by the engineer, steward, and farm bailiff on the work of their departments.

Cardiff.

No remarkable developments are recorded by Dr. E. Goodall in the annual report of the City of Cardiff Mental Hospital for 1923. There has been little change in the number of patients under treatment. The policy of staffing male wards with female nurses is being continued, and it is interesting to note that a number of nurses are being instructed in massage. Research by the pathological staff of three members, who receive grants from the Medical Research Council, has been devoted to the same ends as those referred to in last year's report. They include the estimation of total nitrogen, sugar, and chlorides in the blood and cerebro-spinal fluid of cases of epilepsy, sugar-tolerance tests in epilepsy and general paralysis, an investigation of the toxicity of the blood-serum and corpuscles in acute insanity of various kinds, which has included attempts to produce antibodies by animal inoculations, certain radiographic work on the digestive functions (which has been published and reviewed in our columns[1]), and an "investigation of the bacterial content of the alimentary and urinary tracts," of which insufficient particulars are given to judge of its exact nature. The very large amount of biochemical work carried out during the last few years has been devoted to somewhat unpromising ends, and it is to be hoped that the staff of the best equipped research laboratory in any mental hospital in this country will not be discouraged from breaking some entirely fresh ground by the failure of their work hitherto to produce any definite or illuminating conclusions. It is with some surprise that one reads of a sporadic case of dysentery, from which the stools were sent to the County Public Health Laboratory in Cardiff for bacteriological examination, and the blood for agglutination tests to Oxford. Dysentery is not an uncommon disease in mental hospitals, and it might have been supposed that in an institution so well equipped from the laboratory standpoint as this such work could have been done on the premises.

Birmingham.

The annual report of the asylums committee of the city of Birmingham, as in former years, is a singularly complete and illuminating record of the work at Winson Green, under Dr. C. B. Roscrow, and Rubery Hill, under Dr. T. C. Graves. As an example of its thoroughness may be cited the detailed and enlightened analysis of ætiology in regard not only to the new cases admitted, but to those which recovered during the year. A comparison of these two tables yields no very striking contrasts, but it is interesting to observe that "sepsis" was regarded as a contributory cause in no less than 241 admissions, and had been present in 60 cases which recovered. In order more effectively to cope with bodily conditions whose existence may be supposed to retard recovery, there is now a visiting staff including two throat and aural surgeons, and a gynæcologist, in addition to the dental surgeon. Pathological investigations are, of course, carried out at the Hollymoor Research Laboratory, Hollymoor being an annexe of Rubery Hill. The latter is an old building, and at the present rate of admissions will soon require extension; the Visiting Commissioner expresses the hope that when this is undertaken verandahs, clinical rooms, and other amenities may be included in the plans. His only adverse comment of the administration regards the extensive use of condensed milk in the dietary. Not everyone will agree with Dr. Graves, the medical superintendent of Rubery Hill, in the following observations on occupational treatment: "The subject of employment of mentally afflicted patients has been much under discussion of late, and the term occupational therapy has been devised. I would only remark that prior to the onset of their mental breakdown patients have generally been at work. The proper way to regard employment is as a test of physical and mental capacity during convalescence, in a similar way to that adopted in sanatoria for tuberculosis by graduated exercise and work." The absence of a list of the medical staff is unusual and confusing. In the interest of veracity it should be observed that the possession by all the (assistant) medical officers at Rubery Hill of the Diploma in Psychological Medicine is not a "unique circumstance." At least one other English mental hospital, with a staff of four or five members, possesses this distinction.

Monmouthshire.

In the annual report of the Monmouthshire Asylum, Abergavenny, Dr. N. R. Phillips records a considerable increase in the population of this hospital, which, if continued, will necessitate internal re-arrangement. There is a building, Maindiff Court, which at present remains unused, and several purposes have a claim on it; separate accommodation for recent admissions, and the isolation of the tuberculous, of whom there are 31 known cases in the hospital at the present time, are perhaps the most important. Suggestions from this point of view are made in the report of the Visiting Commissioner, who also criticises the diet, certain mortuary and bathroom arrangements, the system of record-keeping, and the facilities for sterilising foul washing. It is therefore somewhat irritating to read in the remarks of the chairman of the committee that the report of His Majesty's Commissioner "was again quite satisfactory." This report also states that 31 cases of dysentery, with three deaths, occurred between August, 1922, and October, 1923, whereas the report of the medical superintendent observes: "The health of the patients generally was good, and, except for a fatal case of enteric fever and a small amount of colitis, there was no epidemic disease." The death-rate was the lowest on record for the hospital, 5·7 per cent., and the recovery-rate is rising; many patients appear to receive parole and leave on trial, but of the latter very few receive money allowances.

SCHOOL MEDICAL SERVICE.

Leeds.

THE Leeds children of subnormal nutrition are kept under strict observation. They are regularly weighed by the school nurse and the results recorded by graphs. Parents are advised as to diet and treatment where necessary, and if a child does not appear to be making sufficiently rapid progress he is presented for examination by the school doctor. Children having free meals are regularly weighed. The parent of every school child in Leeds has been given a leaflet with sensible advice on broad lines as to food and its value. This is evidently necessary. Of the

39 children examined in the nursery school only one was found to have no defects, the other 38 giving a total of 152 various defects. The necessity for nursery schools in industrial areas is obvious, but this figure is alarming. During the autumn an epidemic of conjunctivitis due to the Koch-Weeks bacillus occurred throughout the schools in the city. Prompt measures were taken, and by the end of the year the number of cases had declined considerably, but the number of attendances for this trouble at the clinic had advanced from 4615 during 1922 to 8707 this year. The Central clinic is now completely housed in one building, with good waiting-room accommodation. The consulting rooms are bright and airy, and the new arrangement will add to the comfort of parents and children as well as to that of the staff. Overcrowding of clinics leads to hasty work, which is bound to depreciate in quality.

An interesting investigation into the incidence of defective vision in the various types of schools is given.

	Per cent.		Per cent.
Elementary schools ..	31·1	Special schools ..	38·2
Secondary schools ..	53·0	Industrial schools	55·1
Day trade schools ..	40·0		

The actual numbers of which the percentage is taken is not given, and therefore no positive deductions can be drawn, but it would be an interesting piece of research to work out the actual incidence of defective vision in these schools and to elucidate the amount of myopia in each. A percentage of 29·9 children was found at routine inspection to require treatment. Dr. Algernon Wear laments the apathy of parents with regard to dental defects. Only 39·1 per cent. of the children with dental disease were dealt with during the year. The report on physical training in Leeds is instructive, and an analysis on broad lines of the graph of school absences given at the end would be most useful.

Dewsbury.

The school medical service in Dewsbury has cost the ratepayers 0·73*d.* in the pound, or 2*s.* 1*d.* per school child. A total of 3929 children were inspected in the schools, while medical and dental consultations altogether amounted to 41,747, not including 4018 visits by nurses to the homes of the children. The average cost of each consultation and inspection, including all necessary treatment, worked out at 5*d.* a head. A special investigation into the question of stammering is being conducted, although so far there does not appear to be any class for treatment of these cases, of whom 24 boys and 13 girls have been examined. Of 1151 children inspected by the school dentist 1002 were referred for treatment, and just over two-thirds of these were actually treated, a considerable increase on last year's figure. Dr. Oscar M. Holden deplores the lack of an open-air school in Dewsbury, which he says is no exception to other industrial towns where the number of undersized men and women at present so obvious would be considerably reduced by facilities for open-air education and healthy living.

Nuneaton.

Dr. K. E. Tapper reports that the five-year-old entrants show a high percentage of defects, and he is endeavouring to bring about a closer coöperation between the school medical service and the maternity and child welfare work in Nuneaton. The school clinic, which is open daily for special inspections, had a total of 5739 attendances made by 1648 children. Chorea, both in the acute and early stages, was prevalent among those attending. There was also a large attendance of dyspeptic cases. At the minor-ailment treatment centre 698 children made altogether 5828 attendances. This clinic is held daily by one of the school nurses, a charge of 6*d.* a week being made. In addition, the school clinic is available for tonsil and adenoid operations, refractions and eye defects, dental and X ray treatment. Chronic ear discharge presents the usual problem, and it is hoped that treatment by ionisation will shortly be available for this condition.

St. Helens.

At the routine medical inspection 28·8 per cent. of children attending elementary schools and 23·8 per cent. attending secondary schools were found suffering from defects requiring treatment. Of elementary school-children 71·5 per cent. and of secondary school-children 59·2 per cent. were treated before the end of the year. Dr. Frank Hauxwell gives an interesting graph showing that a rise or fall in the percentage of the total number of cases treated by the local authority does not always mean an increase or decrease in the total number of cases treated. It is apparent, however, from a close study of the figures given, that the percentage of dental defects treated is falling, and indeed is much smaller than the percentage of medical defects treated. That the annual percentage treated should fall from 60 per cent. in 1920 to 37 per cent. in 1923 is the natural result of the increased number of inspections which have to be carried out. With only one dentist it is impossible to treat more than a certain proportion of the defects found. Dr. Hauxwell attributes the smaller proportion of dental defects treated as compared with medical defects to the apathy of parents and lack of education in this direction, as well as to restricted facilities for treatment. It is obvious that additional dental help is required here.

Lindsey.

Dr. R. Ashleigh Glegg reports that 87 per cent. of the children here require dental treatment, while only 15 per cent. were found to need any other definite treatment. He emphasises the need for further dental help, as at present there is one dentist available for 39,000 children, so that only about 5 per cent. can be treated. Dr. Glegg is anxious to extend the teaching of hygiene in schools and urges that it be given a definite place in the time-table, especially in the upper standards.

Blackburn.

The most important developments during the year have been: (1) The establishment of a residential open-air school for delicate children; (2) the appointment of an orthopædic surgeon, and provision for the after-care of cripples; (3) provision for the retention of enlarged tonsils and adenoids cases in hospital for 48 hours after operation; (4) considerable improvements in the sanitary conditions of many of the schools; (5) extension of health education in schools. Considerable progress has been made in developing a scheme for education in health matters. Topical posters have been exhibited in the schools; a booklet entitled "Health Notes" has been distributed to parents, and 23 health rules have been drawn up and rewards given to children who carry out the greatest number. The treatment for stammering started in August, 1921, was continued. Since the inception of these classes 84 children have been dealt with, and of these 46 had a short revision course. The results are good. Fifty-three speak well and clearly, with no stammer. Fourteen speak with occasional hesitation; nine are improved, and eight made no improvement. In those cases where there was complete failure the result was due, as usual, to indifference on the part of the stammerer and his parents, with a consequent lack of coöperation between the home and the school. Dr. W. Allen Daley reports that over 6000 children were examined during the school year, making, with those who received special inspections and reinspections, a total of 11,544 altogether. Of the code groups 14·6 per cent. were found to require treatment, while of the total number examined 48 per cent. required either treatment or observation.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED SEPT. 6TH, 1924.

Notifications.—The following cases of infectious disease were notified during the week, namely:—Small-pox, 66; scarlet fever, 1419; diphtheria, 662; enteric fever, 108; pneumonia, 419; puerperal fever, 39; cerebro-spinal fever, 4; acute poliomyelitis, 36; acute polio-encephalitis, 3; encephalitis lethargica, 47; typhus fever, 3; dysentery, 5; ophthalmia neonatorum, 121. There were no cases of cholera or plague notified during the week. The 3 cases of typhus fever were notified from St. Helens; 2 cases were notified from the same county borough in the week ended August 16th.

Deaths.—In the aggregate of great towns, including London, there were 5 deaths from enteric fever, none from small-pox, 5 from scarlet fever, 20 from diphtheria, 13 from measles, 17 from influenza. In London itself the diphtheria deaths numbered 8, and the deaths from infantile diarrhœa, which had been 16, 22, and 25 in the preceding three weeks, further increased to 30. A death from typhus was registered from St. Helens.

Fatal Case of Small-pox.—The death of a small-pox case reported during the week ended August 23rd was that of a female infant, aged 3 weeks, whose mother, aged 27, was also suffering from small-pox. Both were unvaccinated. In the case of the mother the rash commenced on August 2nd, and both patients were removed to hospital on August 7th. It is probable that the mother and child were infected shortly after childbirth had occurred. The child was small and wasted, weighing about 5 lb. One or two pustules appeared on the face and fingers; and attempts to vaccinate mother and child were unsuccessful. The child was fed on the bottle with dried milk. In the opinion of Dr. T. E. Francis, medical officer of health for Barnsley, who sends us these details, the small-pox was only a contributory cause of death in this case, the main cause being congenital debility.

PATHOLOGICAL AND BACTERIOLOGICAL LABORATORY ASSISTANTS' ASSOCIATION.

THE first Conference of the Pathological and Bacteriological Laboratory Assistants' Association was held from Sept. 1st to 5th in the Department of Pathology of the University of Edinburgh (by permission of Prof. J. Lorrain Smith), Mr. J. J. Ritchie (Leith) being in the chair.

This Association was founded some years before the war with the object of laying down an educational programme for laboratory assistants.[1] The attendance at the Conference was representative, there being members present from all parts of the country and also from Africa. The local organisation was in the hands of a committee appointed by the Scottish Division of the Association, and a varied programme was arranged.

The Work of the Conference.

Mr. T. D. Hamilton (Edinburgh), the Vice-President, opened the Conference with an address of welcome and read greetings from several overseas members. He then delivered a scholarly lantern lecture on Edinburgh. During the Conference the lectures and demonstrations included the Rockefeller propaganda cinema films Prevention of Malaria (lent by Dr. Andrew Balfour) and Unhooking the Hookworm (lent by Prof. R. T. Leiper); Technique in the Diagnosis of Rabies (A. Norman, Surrey): Demonstration of "Passe Partout" (Tom Read, Manchester); Demonstration of Discharge of Electricity in Gases (Dr. Carse, Edinburgh University); a Rapid Method of Macerating Bone Specimens (F. A. Izzard, Cambridge): the Method of Diagnosing Diphtheria by Toluidine Blue, as used in the Kent County Laboratory (Ernest Arnold, Maidstone): Chromogenic Organisms and Types of Tubercle Bacilli (C. R. Drury, Cambridge); Some Modifications of Staining Processes employed in Laboratory Work (A. Male, London); the Bacteriophage Phenom (d'Herelle) (J. A. Galloway); Demonstration Large Cambridge Microtome (Thomas D. Hamilton, Edinburgh); Demonstration of Various Paraffin Embedding Apparatus (W. Mason, Edinburgh). A paper was read by Mr. T. Dalling, F.R.C.V.S., on Some Small Things that Matter, and J. J. Ritchie (Leith) read a paper on the Bacteriology of Pyorrhœa Alveolaris. An item of particular interest to laboratory workers was a discussion on Laboratory Economics opened by W. A. Mitchell (Cambridge).

A comprehensive exhibition of laboratory work and apparatus was on view during the Conference. Among the various exhibits were longitudinal paraffin sections of a whole human kidney; celloidin sections of a half hemisphere of the brain; photographs, photomicrographs, and lantern slides of pathological conditions; stained sections illustrating various histological staining methods; museum specimens, casts in gelatin, &c. These exhibits were the work of members in the Scottish division.

An exhibition of objects of tropical interest set up by A. Male, W. J. Muggleton, and E. Steele (London) contained excellent specimens illustrating the life-history of parasites and their insect hosts.

Festivities.

At the dinner on the evening of Sept. 5th Prof. A. E. Boycott, the President, made the presentation to Albert Norman, the founder of the Association, of the first Woodhead Medal, together with an address signed by past and present members of the Executive Council.

Mr. Norman, in reply, referred to the fact that the list of officers of the Pathological and Bacteriological Laboratory Assistants' Association was now printed in the list of members of the Pathological Society of Great Britain and Ireland, and pointed out that this was a mark of great confidence on the part of the Pathological Society.

In proposing the toast of "Our President," Mr. Mitchell spoke of the remarkable interest Prof. Boycott had created in the examinations for the Association certificates.

The toast of the health of Mr. and Mrs. Richard Muir was received with enthusiasm, and Mr. Muir replied in reminiscent vein.

During the Conference many places of interest in and around Edinburgh were visited.

The Woodhead Memorial.

The following are the regulations governing the Woodhead Memorial of Pathological and Bacteriological Assistants' Association:—

1. That the sum (not yet complete) collected from members of the Pathological and Bacteriological Laboratory Assistants' Association and others, invested in trustee securities and known as the Woodhead Prize Fund, be kept as a separate account in the funds of the Association.

2. The administration of the Fund and the award of the Woodhead Prize and Medal shall be entrusted to a committee composed of the secretary to the Council of the Association, the secretary to the Examining Council, or their nominees (to be approved by the Council of the Association), and two registered members not necessarily officers of the Association, appointed by the Council of the Association. The president for the time being shall be asked to act as chairman.

3. At the discretion of the Woodhead Memorial Committee the prize, which shall include the Woodhead Prize Medal, and such cash value from the accumulated interest as the Committee shall determine, may be awarded annually or at intervals of a period of years.

4. By agreement between the Council of the Association and the Committee, the Medal may be given for conspicuous services to laboratory workers; the recipient need not necessarily be a member of the Pathological and Bacteriological Laboratory Assistants' Association.

5. When the Memorial Committee offers the Prize to competition at least six months' notice of the conditions shall be published in the *Laboratory Journal*. Competitions shall be open only to members of the Association. The Memorial Committee shall not be bound to award the Prize when in their judgment no competitor merits it.

A total of £141 has been received for the Fund, it has been decided to close the subscription list ct. 15th.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 20, 1924.

SUN AND AIR IN LONDON.

A POWERFUL factor in the health of the metropolis is provided by the parks and open spaces under the control of the London County Council. These number over 100, and cover more than 5000 acres in extent. They vary in size from such places as Hampstead Heath and Blackheath, which thrust their way into the sunny and purer upper atmosphere of London, down to the hardly-won colour and greenery of a disused burial ground in the congested slum areas. An enlightened policy in dealing with this public property means much to the physical and moral well-being of London citizens as a whole. Owing to the unsystematic development of the urban area, parks and open spaces have not been automatically provided in the lay-out, but a broader outlook on the health needs of the community is being followed in the development of new areas, and the painfully slow process of adapting outworn conditions to modern ideas should not press so heavily on the next generation.

The main facts regarding London parks and open spaces are engagingly set out in one[1] of a new series of handbooks issued by the County Council. The parks are so arranged as to cater for the tastes of the public in all possible directions, and the recent debates on the question of allowing Sunday games in them afforded the public an opportunity of realising the enormous value of sunshine and air for the recreation and health of young Londoners. Other bodies control open spaces in the metropolitan area, but on the L.C.C. as paramount public health authority rests the responsibility for the prevention and treatment of disease by healthy environment. The Parks and Open Spaces Committee has long had Dr. ALAN RANDLE among its members, and concerted action is taken between this and other committees of the Council in the use of the parks for health. For example, the Education and Parks Committees together arrange for open-air schools for delicate children, which save the ratepayer the alternative of prolonged treatment in hospital or sanatorium. The healing power of the sun, convincingly shown in the Alps, is now beginning to attract the attention that it so richly deserves, and little by little London is learning to value the sun's rays that it has. Alton and Carshalton are convinced users, and the borough of Bermondsey is now seeking to set up a scheme for treatment of cases approved by the medical officer. Those acquainted with this borough will realise that if heliotherapy is possible in such a district, there is a great future for it in London, for on days when direct sunlight is not available the artificial sun can still be used, combined with open air. All who lived in London during the last big coal strike can recall the clearer air and brighter sky which then prevailed and the public should unite to strengthen the hands of the County Council in getting more adequate powers to combat the smoke nuisance. It is not enough to be able to say that London is the healthiest city ever known; as knowledge extends, that knowledge must be applied for the benefit of all citizens and the sunshine must be brought right into the homes of the people.

There is one aspect of the use of the parks which has to be constantly borne in mind by the Parks and Open Spaces Committee, and that is the feeling of the general public, which would resent any use by the authorities of open spaces for cases looked on as infective. The public regards as such any variety of tuberculosis and would require complete reassurance that no case dangerous to the general well-being was being treated in a place set aside for public recreation. The allotment of sufficient space to secure adequate privacy for a solarium would itself require careful consideration. Public interest in this matter requires just such stimulus as may be gained by a study of the L.C.C. handbook. Meanwhile, this year it has been a question of "First catch your sun."

PURE BACTERIOLOGY.

THE institution of a course of instruction leading to an examination for a diploma in bacteriology by the University of Manchester is an event of some importance. The study of the subject began along technological lines and mostly in relation to bacteria as causes of disease, and the field thus defined has been pretty faithfully cultivated. Development has been in natural sequence to the fundamental impression made by PASTEUR. LEEUWENHOEK knew about bacteria but no one took much interest in them until PASTEUR showed that they really mattered in ordinary human life. Hence in general, and perhaps more so in this country than in some others, "bacteriology" has been practically synonymous with "pathological bacteriology," and attention has been concentrated on the relatively insignificant number of species which live in the altogether specialised habitats necessary to their parasitic and semiparasitic modes of life. Of late considerable progress has been made in technological studies in other fields—agriculture, milk and its products, leather, and so on—and the wider outlook thus attained has proved of great advantage in helping us to understand what bacteria are and how they live. But it is quite clear that progress cannot be made indefinitely in this haphazard way and that the time has come when bacteria must be studied as such. Pathological bacteriology is now hampered everywhere by the absence of knowledge on fundamental biological matters. It is, for example, not known how bacteria multiply and whether there is, sometimes or always, something in their life-history which corresponds to a sexual mode of reproduction. This problem is intimately connected with another series of conundrums for the solution of which the epidemiologist waits—questions of variability, mutation, and transmutation. There is no botanical answer if the hygienist asks, What is a "species" of bacillus? Biologically the advantage of this wider study is equally obvious, for bacteria occupy a unique position among live things in respect of their variety of modes of life and their rapidity of multiplication; hours and days and years to a bacillus and to a man are so different quantitatively that they are almost qualitatively distinct. Bacteriology is, then, full of unsolved problems of a nature which may be called botanical, and its future progress depends largely on their solution.

The way in which practice has outrun knowledge is detrimental too in another way. So practically useful has bacteriology proved that those who engage with it are much too often overwhelmed with diagnostic tests. In many cases universities have been so captivated with this aspect of the subject that they have actually exploited it vigorously for the financial support of the department and even in some instances

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED SEPT. 6TH, 1924.

Notifications.—The following cases of infectious disease were notified during the week, namely:—Small-pox, 66; scarlet fever, 1419; diphtheria, 662; enteric fever, 108; pneumonia, 419; puerperal fever, 39; cerebro-spinal fever, 4; acute poliomyelitis, 36; acute polio-encephalitis, 3; encephalitis lethargica, 47; typhus fever, 3; dysentery, 5; ophthalmia neonatorum, 121. There were no cases of cholera or plague notified during the week. The 3 cases of typhus fever were notified from St. Helens; 2 cases were notified from the same county borough in the week ended August 16th.

Deaths.—In the aggregate of great towns, including London, there were 5 deaths from enteric fever, none from small-pox, 5 from scarlet fever, 20 from diphtheria, 13 from measles, 17 from influenza. In London itself the diphtheria deaths numbered 8, and the deaths from infantile diarrhœa, which had been 16, 22, and 25 in the preceding three weeks, further increased to 30. A death from typhus was registered from St. Helens.

Fatal Case of Small-pox.—The death of a small-pox case reported during the week ended August 23rd was that of a female infant, aged 3 weeks, whose mother, aged 27, was also suffering from small-pox. Both were unvaccinated. In the case of the mother the rash commenced on August 2nd, and both patients were removed to hospital on August 7th. It is probable that the mother and child were infected shortly after childbirth had occurred. The child was small and wasted, weighing about 5 lb. One or two pustules appeared on the face and fingers, and attempts to vaccinate mother and child were unsuccessful. The child was fed on the bottle with dried milk. In the opinion of Dr. T. E. Francis, medical officer of health for Barnsley, who sends us these details, the small-pox was only a contributory cause of death in this case, the main cause being congenital debility.

PATHOLOGICAL AND BACTERIOLOGICAL LABORATORY ASSISTANTS' ASSOCIATION.

THE first Conference of the Pathological and Bacteriological Laboratory Assistants' Association was held from Sept. 1st to 5th in the Department of Pathology of the University of Edinburgh (by permission of Prof. J. Lorrain Smith), Mr. J. J. Ritchie (Leith) being in the chair.

This Association was founded some years before the war with the object of laying down an educational programme for laboratory assistants.[1] The attendance at the Conference was representative, there being members present from all parts of the country and also from Africa. The local organisation was in the hands of a committee appointed by the Scottish Division of the Association, and a varied programme was arranged.

The Work of the Conference.

Mr. T. D. Hamilton (Edinburgh), the Vice-President, opened the Conference with an address of welcome and read greetings from several overseas members. He then delivered a scholarly lantern lecture on Edinburgh. During the Conference the lectures and demonstrations included the Rockefeller propaganda cinema films Prevention of Malaria (lent by Dr. Andrew Balfour) and Unhooking the Hookworm (lent by Prof. R. T. Leiper); Technique in the Diagnosis of Rabies (A. Norman, Surrey); Demonstration of "Passe Partout" (Tom Read, Manchester); Demonstration of Discharge of Electricity in Gases (Dr. Carse, Edinburgh University); a Rapid Method of Macerating Bone Specimens (F. A. Izzard, Cambridge): the Method of Diagnosing Diphtheria by Toluidine Blue, as used in the Kent County Laboratory (Ernest Arnold, Maidstone); Chromogenic Organisms and Types of Tubercle Bacilli (C. R. Drury, Cambridge); Some Modifications of Staining Processes employed in Laboratory Work (A. Male, London); the Bacteriophage Phenomena (d'Herrelle) (J. A. Galloway); Demonstration on the Large Cambridge Microtome (Thomas D. Hamilton, Edinburgh); Demonstration of Various Paraffin Embedding Apparatus (W. Mason, Edinburgh). A paper was read by Mr. T. Dalling, F.R.C.V.S., on Some Small Things that Matter, and J. J. Ritchie (Leith) read a paper on the Bacteriology of Pyorrhœa Alveolaris. An item of particular interest to laboratory workers was a discussion on Laboratory Economics opened by W. A. Mitchell (Cambridge).

A comprehensive exhibition of laboratory work and apparatus was on view during the Conference. Among the various exhibits were longitudinal paraffin sections of a whole human kidney; celloidin sections of a half hemisphere of the brain; photographs, photomicrographs, and lantern slides of pathological conditions; stained sections illustrating various histological staining methods; museum specimens, casts in gelatin, &c. These exhibits were the work of members in the Scottish division.

An exhibition of objects of tropical interest set up by A. Male, W. J. Muggleton, and E. Steele (London) contained excellent specimens illustrating the life-history of parasites and their insect hosts.

Festivities.

At the dinner on the evening of Sept. 5th Prof. A. E. Boycott, the President, made the presentation to Albert Norman, the founder of the Association, of the first Woodhead Medal, together with an address signed by past and present members of the Executive Council.

Mr. Norman, in reply, referred to the fact that the list of officers of the Pathological and Bacteriological Laboratory Assistants' Association was now printed in the list of members of the Pathological Society of Great Britain and Ireland, and pointed out that this was a mark of great confidence on the part of the Pathological Society.

In proposing the toast of "Our President," Mr. Mitchell spoke of the remarkable interest Prof. Boycott had created in the examinations for the Association certificates.

The toast of the health of Mr. and Mrs. Richard Muir was received with enthusiasm, and Mr. Muir replied in reminiscent vein.

During the Conference many places of interest in and around Edinburgh were visited.

The Woodhead Memorial.

The following are the regulations governing the Woodhead Memorial of Pathological and Bacteriological Assistants' Association:—

1. That the sum (not yet complete) collected from members of the Pathological and Bacteriological Laboratory Assistants' Association and others, invested in trustee securities and known as the Woodhead Prize Fund, be kept as a separate account in the funds of the Association.

2. The administration of the Fund and the award of the Woodhead Prize and Medal shall be entrusted to a committee composed of the secretary to the Council of the Association, the secretary to the Examining Council, or their nominees (to be approved by the Council of the Association), and two registered members not necessarily officers of the Association, appointed by the Council of the Association. The president for the time being shall be asked to act as chairman.

3. At the discretion of the Woodhead Memorial Committee the prize, which shall include the Woodhead Prize Medal, and such cash value from the accumulated interest as the Committee shall determine, may be awarded annually or at intervals of a period of years.

4. By agreement between the Council of the Association and the Committee, the Medal may be given for conspicuous services to laboratory workers; the recipient need not necessarily be a member of the Pathological and Bacteriological Laboratory Assistants' Association.

5. When the Memorial Committee offers the Prize to competition at least six months' notice of the conditions shall be published in the *Laboratory Journal*. Competitions shall be open only to members of the Association. The Memorial Committee shall not be bound to award the Prize when in their judgment no competitor merits it.

A total of £141 has been received for the Fund, and it has been decided to close the subscription list on Oct. 15th.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 20, 1924.

SUN AND AIR IN LONDON.

A POWERFUL factor in the health of the metropolis is provided by the parks and open spaces under the control of the London County Council. These number over 100, and cover more than 5000 acres in extent. They vary in size from such places as Hampstead Heath and Blackheath, which thrust their way into the sunny and purer upper atmosphere of London, down to the hardly-won colour and greenery of a disused burial ground in the congested slum areas. An enlightened policy in dealing with this public property means much to the physical and moral well-being of London citizens as a whole. Owing to the unsystematic development of the urban area, parks and open spaces have not been automatically provided in the lay-out, but a broader outlook on the health needs of the community is being followed in the development of new areas, and the painfully slow process of adapting outworn conditions to modern ideas should not press so heavily on the next generation.

The main facts regarding London parks and open spaces are engagingly set out in one[1] of a new series of handbooks issued by the County Council. The parks are so arranged as to cater for the tastes of the public in all possible directions, and the recent debates on the question of allowing Sunday games in them afforded the public an opportunity of realising the enormous value of sunshine and air for the recreation and health of young Londoners. Other bodies control open spaces in the metropolitan area, but on the L.C.C. as paramount public health authority rests the responsibility for the prevention and treatment of disease by healthy environment. The Parks and Open Spaces Committee has long had Dr. ALAN RANDLE among its members, and concerted action is taken between this and other committees of the Council in the use of the parks for health. For example, the Education and Parks Committees together arrange for open-air schools for delicate children, which save the ratepayer the alternative of prolonged treatment in hospital or sanatorium. The healing power of the sun, convincingly shown in the Alps, is now beginning to attract the attention that it so richly deserves, and little by little London is learning to value the sun's rays that it has. Alton and Carshalton are convinced users, and the borough of Bermondsey is now seeking to set up a scheme for treatment of cases approved by the medical officer. Those acquainted with this borough will realise that if heliotherapy is possible in such a district, there is a great future for it in London, for on days when direct sunlight is not available the artificial sun can still be used, combined with open air. All who lived in London during the last big coal strike can recall the clearer air and brighter sky which then prevailed and the public should unite to strengthen the hands of the County Council in getting more adequate powers to combat the smoke nuisance. It is not enough to be able to say that London is the healthiest city ever known; as knowledge extends, that knowledge must be applied for the benefit of all citizens and the sunshine must be brought right into the homes of the people.

There is one aspect of the use of the parks which has to be constantly borne in mind by the Parks and Open Spaces Committee, and that is the feeling of the general public, which would resent any use by the authorities of open spaces for cases looked on as infective. The public regards as such any variety of tuberculosis and would require complete reassurance that no case dangerous to the general well-being was being treated in a place set aside for public recreation. The allotment of sufficient space to secure adequate privacy for a solarium would itself require careful consideration. Public interest in this matter requires just such stimulus as may be gained by a study of the L.C.C. handbook. Meanwhile, this year it has been a question of "First catch your sun."

PURE BACTERIOLOGY.

THE institution of a course of instruction leading to an examination for a diploma in bacteriology by the University of Manchester is an event of some importance. The study of the subject began along technological lines and mostly in relation to bacteria as causes of disease, and the field thus defined has been pretty faithfully cultivated. Development has been in natural sequence to the fundamental impression made by PASTEUR. LEEUWENHOEK knew about bacteria, but no one took much interest in them until PASTEUR showed that they really mattered in ordinary human life. Hence in general, and perhaps more so in this country than in some others, "bacteriology" has been practically synonymous with "pathological bacteriology," and attention has been concentrated on the relatively insignificant number of species which live in the altogether specialised habitats necessary to their parasitic and semiparasitic modes of life. Of late considerable progress has been made in technological studies in other fields—agriculture, milk and its products, leather, and so on—and the wider outlook thus attained has proved of great advantage in helping us to understand what bacteria are and how they live. But it is quite clear that progress cannot be made indefinitely in this haphazard way and that the time has come when bacteria must be studied as such. Pathological bacteriology is now hampered everywhere by the absence of knowledge on fundamental biological matters. It is, for example, not known how bacteria multiply and whether there is, sometimes or always, something in their life-history which corresponds to a sexual mode of reproduction. This problem is intimately connected with another series of conundrums for the solution of which the epidemiologist waits—questions of variability, mutation, and transmutation. There is no botanical answer if the hygienist asks, What is a "species" of bacillus? Biologically the advantage of this wider study is equally obvious, for bacteria occupy a unique position among live things in respect of their variety of modes of life and their rapidity of multiplication; hours and days and years to a bacillus and to a man are so different quantitatively that they are almost qualitatively distinct. Bacteriology is, then, full of unsolved problems of a nature which may be called botanical, and its future progress depends largely on their solution.

The way in which practice has outrun knowledge is detrimental too in another way. So practically useful has bacteriology proved that those who engage with it are much too often overwhelmed with diagnostic tests. In many cases universities have been so captivated with this aspect of the subject that they have actually exploited it vigorously for the financial support of the department and even in some instances the partial maintenance of other activities. Such a practice is obviously far from the university ideal, and to it may be attributed in large part the present stagnation of the science in which no discovery of first-rate importance has been made for many years. The hygienic importance of diagnostic bacteriology is beyond question, and if it was in the proper hands—i.e., those of the medical officers of health—it would achieve even more usefulness than it has done already. But to employ those who should be finding and teaching in bacteriology to earn money is as bizarre a proceeding as it would be to charge the professors of Greek and mathematics with the duties of furnishing inscriptions for tombstones and checking the calculations of insurance companies. What there is most needed at the present time by all those who are engaged on the technological applications of bacteriology is the provision of facilities for teaching and research into how bacteria, irrespective of their human importance, live and move and have their being. How this would best be arranged no doubt varies with local circumstances; it may be in the department of hygiene or better in the department of botany. The course and diploma at Manchester are a small beginning along the right lines; we wish Prof. W. W. C. Topley all success with his enterprise.

[1] London Parks and Open Spaces. With a Foreword by Sir James Bird. University of London Press. 1s.

MILK PROBLEMS.

The Director of Water Examination may boast of the apparent ease and regularity with which London's seven million persons are supplied with water fit to drink. There is no director of milk examination for London or elsewhere, and if there were he would hang his head. The annual report of the chief medical officer for the Ministry of Health, whose remarks on the milk problem are summarised on p. 620, states that a beginning has been made in setting up new ideals in the milk trade by means of the "grading" Order. It is only a small beginning. There are now, for instance, only enough cows in the country guaranteed free from tuberculosis by the tuberculin test to supply a population of 50,000 with a pint of milk each per day. The reports of medical officers of health as they come in show that the introduction of the Order has excited little or no interest in most districts. The National Milk Publicity Council has its work before it.

The milk problem as it exists to-day, like the slum problem, is a modern one. Before the days of railways the consumer lived near the producer, the milk was delivered fresh, the dairy farms were small, the farmer's wife superintended the dairy, and his daughter did the milking. The labour was therefore of a superior type. With urbanisation and railways the farms became bigger, larger herds of cows were kept, milk no longer fresh was delivered in bulk, and the conduct of milking operations was handed over to labourers. For a long time the dairy farms remained in the towns, the herds were increased in size and housed in buildings not intended for the purpose, and tended by labour unversed in traditions of dairy cleanliness. The new conditions make necessary an even greater regard for cleanliness than in pre-railway days. The first essential therefore is education of the dairy farmer and his staff by means of agencies such as the Reading Institute—such an institute would be welcome in every dairying district—by clean milk competitions and by the efforts of county agricultural organisers. Sir George Newman remarks that the consumer can demand clean milk, the trade has shown that it can supply it, and each local authority should see that it does. But what are the facts? Although there may be sporadic signs of interest, the public as a whole is apathetic. Only a small section will agitate; the majority will content themselves with neglecting milk as an article of food unless its quality improves. No doubt if improvement occurred they would welcome it and gradually learn to use more milk. Nor have local authorities taken more interest in the matter. The milk produced in their areas is consumed elsewhere, they have been content to leave it to the farmer to satisfy his customers. Some county councils interest themselves in organising clean milk competitions, and in trying to get the district councils to combine for the appointment of veterinary inspectors. Most rural councils, however, imitate the Ministry of Agriculture in their tender treatment of agricultural interests. There are encouraging signs that the Ministry is beginning to see that the interests of the consumer and producer coincide in this matter and that a larger consumption of milk depends upon the production of a better article. Some stimulus must be provided to induce the authority supervising dairies and cowsheds to do its duty. It is open to discussion whether this object would better be secured by grants-in-aid or by transference of the responsibility from the district to the county councils.

There are statutes and Orders which would improve the condition of the milk-supply if they could be put in force. The Council of the British Medical Association recently, however, decided that the time was inopportune to press upon the Government the operation of the Milk and Dairies Act and the Tuberculosis Order of 1914. We do, however, most cordially agree with Dr. H. G. Dain, who spoke strongly on the subject at the annual meeting in Bradford, that the question of the sale of milk containing tubercle bacilli must not be shelved any longer. The position taken up by Dr. Dain is substantially as follows: As a profession we are not primarily concerned with the cost, nor are we tied to a particular method, of stopping the sale of tubercle-infected milk, although it might reasonably be made an offence to sell such milk when the addition of so harmless an impurity as water is punishable and when the vendor whose milk disseminates typhoid soon finds himself in trouble with the sanitary authority. We are told that tuberculosis in cattle is so prevalent that to eliminate all tuberculous animals would practically destroy our herds and do away with our milk-supply. To begin by searching for and destroying tuberculous cattle, compensating their owners for the loss, is not economically sound and is to attack the problem from the wrong end. The cost of tuberculosis to the community may be illustrated by the case of a boy, cured of tuberculous hip disease, whose treatment over a period of five years, including a final osteotomy to correct deformity, had cost £500 apart from any medical or surgical fees. The agriculturist, faced some years ago with a disease in potatoes which threatened the whole industry, soon discovered immune varieties of the tuber. In so serious a matter as the stamping out of tuberculosis every effort should be directed towards breeding cattle less subject to this disease. Dr. Dain's objection to reliance on the grading of milk for elimination of tubercle is that the bulk of the poorer working-class population would continue to drink the lower grades as being less costly, and the net result of grading would be to provide the well-to-do with the opportunity of escaping calamities which their poorer brethren could not avoid. Why should it not be made a punishable offence to offer for sale milk containing tubercle bacilli? It is to-day, Dr. Dain has the courage to insist, a perfectly practical thing to do.

A SUCCESSFUL ANTI-GOITRE CAMPAIGN.

In a little handbook[1] on first principles in business, Mr. A. F. Shepherd, whose services to hospital campaigns are well known, states that the only practical method whereby one can arrest attention, create interest, carry conviction, arouse desire, and move a composite public to a desired course of action, is through the process of carefully planned educational publicity suited to the present-day sociological structure. Medicine has had too few successes to record in publishing health, although Sir George Newman may be right in claiming for educational methods some share in the striking improvement of vital statistics in this country during the last decade.

Two examples reach us from abroad. The little Canton of Appenzell has been the scene during the last two years of a remarkable demonstration in health publicity. Dr. Henry Hunziker, of Adliswil, and Dr. Hans Eggenberger, of Herisau, being convinced that the ætiological prophylaxis of goitre has been solved, as they say, with as great a degree of certainty as the question of the roundness of the earth, set about inducing the 30,000 rural folk in the canton to make a habit of taking the additional modicum of iodine necessary to rid them of goitre. The simple method chosen was to add a small proportion of potassium iodide to the salt supplied by the dry-goods man. It was impossible to make this substitution compulsory, inasmuch as medical opinion in the canton was not unanimous; Dr. Eggenberger, therefore, toured the canton and gave lantern lectures in almost all the villages. Over 10 per cent. of the population took part in the discussions which followed. Both kinds of salt are on sale in the canton, the iodised salt costing two Rappen—that is to say, about one farthing—more per kilo; but as the accompanying graph clearly shows. his publicity campaign resulted

passed away, it came out that the dealer in question had nothing but iodised salt to sell; and, when this was explained to the patient, she was cured not only of her palpitation but also of her prejudice. A year previously this woman had borne in hospital a child with large congenital struma compressing the trachea; a year later, during which she took iodised salt, a lusty infant was born to her without palpable thyroid. Dr. Hunziker will only admit to having seen two patients with transient thyroid symptoms from iodism. Both were taking iodised salt, but one had consumed also three bottles of Wildegger iodine water and the other had taken chocolate tablets of iodostarin, both of which increased the iodine ration by one hundred times or more. The result of the campaign, as Dr. Hunziker sets out, after two years' experience, is that no goitrous being comes into the world, and no new goitres develop in Appenzell. Measurement of existing goitres shows a diminution in all the young forms and some of the older. Iodised salt, in the author's opinion, is to be regarded not as a medicine but as a food which is able to free Switzerland and other goitrous countries from goitre and cretinism. On a small scale the result certainly seems to be as striking as the claim.

The second example is in progress in New Zealand where the problem of goitre is urgent, and the iodine theory, if not universally accepted, is being tested with provisional conviction. Prof. A. M. Drennan, of Dunedin, is working on the relation to goitre of iodine in the soil and in vegetables grown on that soil, but is not prepared yet with a final answer. In a volume of studies[3] from the Otago Medical School, Dr. C. E. Hercus and Dr. E. S. Baker analyse the rival theories for the origin of endemic goitre and find in New Zealand the geological aspect of the problem alone worthy of further consideration. It is along river valleys, on plains formed from sedimentary deposits out of which soluble salts have been washed, that endemic goitre occurs. In such areas a census has shown a high percentage of thyroid hypertrophy in the fifth year of life with increased incidence,

Annotations.

"Ne quid nimis."

THE VITAL STATISTICS OF 1923.[1]

WHATEVER advantages the present system of issuing the matter once contained in a single volume in three may possess, to the journalist it is an unmixed evil. He must either abstain from comment or run the risk of doing ill what Dr. T. H. D. Stevenson will do well in another instalment of the official records. Yet we cannot pass this great, this impressive record without a word. In 1923, 444,785 persons died, the smallest total of deaths since 1862, when the population was little more than twenty millions—now it is more than thirty-eight millions. The standardised death-rate was 10·3 per 1000, less than half what it was in 1841–50, 40 per cent. short of the death-rate Farr proposed as an attainable but unattained ideal 50 years ago. The rate of mortality in childhood, ages 0–5, is one-third of what it was in 1841–50, the rate of infant mortality has declined from 153 to 69 per 1000 births. The rate of mortality from tuberculosis (persons), which was 1352 per million living in 1913, was 1062 in 1923. This story is repeated in so many lines of the figures, the improvement is so general that one is reminded of Polycrates and seeks for a ring to sacrifice, for some sign of a deterioration which may propitiate the envy of the gods. Of course, the layman will find it without any seeking in the advancing death-rate from cancer; more deaths from cancer occurred in 1923 (22,065 men, 26,603 women) than in any previous year; the death-rate was 19 per cent. higher than in 1913. Yet the gods may think the sacrifice insufficient, for at the later ages of life, the ages when mortality from cancer becomes considerable, the general death-rate has been reduced very greatly. For instance, 48 per cent. of deaths of males from cancer, and 46 per cent. of deaths of women from cancer, occurred between the ages of 45 and 65. Taking as the standard of comparison so recent a year as 1913, we find that the death-rate in 1923 of males aged 45–55 years was 74 per cent., and of males aged 55–65, 78 per cent. of the rates in 1913; the percentage ratios for women are also 74 and 78. The increase in rate of mortality from cancer is so much over-compensated by the decreased risk of dying from other causes that even at the cancer ages the likelihood of dying at all within a year is less than it has ever been. It is hardly necessary to suppose that our bad habits of drinking hot tea, paying no heed to our colons, and generally neglecting the warnings of prophets within and without the medical profession, have really increased the powers of the cancer dragon; but that it really is a dragon can hardly remain in doubt after a visit to the British Empire Exhibition. For suppose a population of distressed damsels exposed to the ravages of a dragon and of a well-directed battery of machine guns; then since, according to the best mediæval authorities, dragons only devour living maidens, the rate of mortality per machine gun is likely to exceed the mortality *per draconem*. Now expose a population of the same size, or larger, to a dragon of equal appetite and no competitors, then, unless we suppose that the old dragon ate not only as many as he could but also as many as he would, the new rate of dragon mortality will be absolutely as well as relatively much higher than before. In fact, even an increasing *rate* of mortality from cancer, if associated with a decreasing rate of mortality from all causes, does not involve as a logical consequence any absolute increase of cancro-genetic factors at all. Perhaps then we should seek our object of sacrifice in the increasing mortality from encephalitis lethargica, and in the still large attribution of deaths to influenza; the number dying from the latter in 1923 was much smaller than in 1922, but exceeded 8000. Indeed, it cannot be proved that the development of some new infection or the transformation and increase of virulence of some old infection might not bring back the rates of mortality of 50 or 100 years ago. Such a thing has happened before: England in the fourteenth century, Rome in Justinian's time no doubt had far higher death-rates than in earlier times. The thing *may* happen; but the most pessimist philosopher would hardly aver that it is likely to happen, having regard to the relatively small success of the onslaught in 1918 of influenza and the recovery made by our general death-rate since then.

DENTAL DRESSERS IN DERBYSHIRE.

THE Derbyshire scheme for dental treatment by means of school dentists, aided by dental dressers who have had 12 months' training at school clinics and who act only under the personal supervision of a registered dentist, appears to have worked well, judging from the tables of comparative statistics for various counties given in the annual report of the school medical officer for 1923. Nevertheless, the scheme may lapse at the end of this year unless the Order issued by Sir Alred Mond in August, 1922, is modified. Dr. Sidney Barwise pleads for an extension of the time-limit until more dentists are available. He outlines the New Zealand scheme, which differs in important particulars from that in Derbyshire; for in New Zealand dental dressers after two years' training in a dental hospital may work quite apart from the registered school dentist. Indeed, there are in the New Zealand Service only eight qualified dentists. The difficulty appears to be purely a question of coping with the enormous amount of work involved in the treatment of the teeth of our large school population. There is, evidently, no fear of the work being scamped, provided the services of the right type of registered dentist are available for supervision and training. The testimony of dentists of the highest standing who have been in constant touch with the work of these dressers, and the X ray photographs of fillings reproduced in the report, are ample guarantee of the quality of work done. At present there are not sufficient dentists to go round, and there is little prospect of the number increasing to an extent sufficient for the country, more especially the rural districts, while children's teeth are in a notoriously bad state, 80 per cent. at least of the school population requiring treatment. The Derbyshire scheme is running smoothly and effectively, and the teeth of the Derbyshire children are being properly attended to—the numbers given in the comparative tables speak for themselves—so that it seems a pity to disturb the scheme until an adequate substitute is available. The dental dressers are well-educated intelligent girls of matriculation standard; they work only under the personal supervision of a registered dentist, and Dr. Barwise is of opinion that their work should not be limited to "cleaning and polishing, applying or removing dressings or temporary fillings, charting, recording, and work of like responsibility" as laid down by the Mond Order, but that they should be allowed to continue doing the dental work of a routine character such as (*a*) the examination of children's teeth with a probe and mirror, (*b*) extraction and treatment of temporary teeth, (*c*) treatment of the first permanent molars, the remaining responsible work being left to a registered dentist. The trouble is, Dr. Barwise says, that unless the dental dresser is allowed to do those things she is really not of much use. A registered dentist under the new Order may undertake operative work while supervising the work of two dental dressers. If not operating he may supervise the work of six dressers, all cleaning, polishing, applying or removing dressings or temporary fillings, charting, and recording, but meanwhile no one is doing the permanent fillings or extractions which make up the bulk of the school medical work. By preventive measures, that is by intensive work on the younger age-groups, it ought to be possible in a few years to reduce the operative work necessary among school-children to dimensions proportionate to the number of dentists available, but at present owing to the enormous demand of the older children in a great many districts this is quite impossible. The Derbyshire scheme meets this situation and is devoid of possible abuse, for the dental dressers are trained at the school clinics by the school dentists, and there is no possibility of their ever establishing themselves in opposition to the registered practitioner.

A BIOGENETIC VIEW OF INSANITY.

DURING the period 1901–13 the admissions to the mental ward of the Eastern District Hospital, Glasgow, included some thousands of insane patients who were treated under hospital conditions without certification. An account of this enterprise, and of its bearing on the great problems connected with the treatment of the insane, was given by Dr. John Carswell in a Maudsley lecture[1] delivered before the quarterly meeting of the Medico-Psychological Association in May last. Since proposals for instituting similar treatment in England are under consideration and trial at the present time in various places, the conclusions drawn by Dr. Carswell demand investigation. The statistics referring to patients are composed of figures so large that their significance is, at least on that ground, unassailable. They show that there was no important variation in the ratio of insane to the total population throughout the period during which the experiment was under trial, and that the incidence of insanity was not remarkably greater in districts with a death-rate above the average for the city than in those, presumably healthier and better-to-do, areas whose death-rate was below the normal. These figures refer to the age-period 15–45, but over the age of 45 the incidence of insanity is considerably higher in the poorer districts (assuming that a high death-rate indicates poverty). Now, Dr. Carswell regarded the large majority of his cases under 45 as due to "constitutional instability," by which he appears to mean a congenital, as opposed to an environmental, cause, and from the foregoing data it would appear that hereditary causes are equally operative among the poor and the well-to-do. On this ground he opposes the contention that "improvement of social conditions means the preservation of the unfit, and consequently a higher producton of insanity." Here we are on ground common to medicine and statesmanship, contentious enough even at the present time, and closely connected with the problem of over-population, which bids fair in time to overshadow every other political issue. For that reason Dr. Carswell's contribution is the more welcome. But perhaps the question is not as simple as he would have us believe. It has not been shown, for example, that physical and mental "unfit"-ness are parallel phenomena, nor do the "eugenic" arguments to which he takes so strong an objection refer solely to the latter type. If there is any sort of mental disorder notably more common in the lower classes than in any other, it is that of the minor degrees of mental defect, often compatible with an efficient life of manual labour, but precluding any more skilled or responsible work; these men and women are outside the scope of Dr. Carswell's figures, because they never receive institutional care. The reply of the eugenist to Dr. Carswell would be that his object is to eradicate the mentally defective and unstable from any and every class; "better social conditions" are only deplorable in this sense, in so far as they enable the mentally defective to propagate freely, a qualification which demands much closer consideration of what exactly is involved in these better conditions. Nor can we unreservedly accept Dr. Carswell's statistics as to ætiology. "Constitutional disability" (adolescence, congenital defect, heredity, epilepsy, and the climacteric), "toxic causes" (syphilis, alcoholism, exhaustion states, and the effects of acute bodily diseases), "gross brain diseases," and "senile changes," are held so largely accountable for his 909 cases of well-ascertained ætiology that "all other factors in the production of insanity are practically negligible as contributory elements in the total mass of insane persons." Do we really understand insanity as well as this dogmatic statement would imply? It has been said that a man may have syphilis and a broken neck; may it not also be said that a man may be an alcoholic, or exhausted, or convalescent from an acute bodily illness, and yet become insane from quite another cause? In extending the hypothesis of "biogenetic" origin to most forms of insanity occurring before the age of 45, Dr. Carswell presents insanity in the light of an affliction singularly unamenable to the prophylactic measures which are summed up in the expression "mental hygiene." We believe that to discount the psychogenic element in acquired insanity, to accept any obvious antecedent morbid conditions as a sufficient explanation for it, is to go far beyond our knowledge of its real origins, and with every respect for the magnificent volume of work represented in these figures, it must be submitted that, to the extent that they depend on views of ætiology, the conclusions to which they lead can only be accepted with reserve.

THE PHOTOGRAPHIC EXHIBITION.

THE sixty-ninth annual exhibition of the Royal Photographic Society, opened at the galleries of the Society, 35, Russell-square, W.C., on Sept. 13th, is a very brilliant one, well in advance of its immediate predecessors and a remarkable contrast to those with which we were familiar before the war. The contrast has particular reference to the striking advance made in the application of photography in various technical directions, in medicine and in science generally, in trades and manufactures in an infinite number of ways. Whilst the pictorial side of the art has not been neglected, the scientific and technical section now represents the greater part of the exhibition. It is amusing and instructive to remember that some 12 or 15 years ago this section occupied a few feet of wall space in a remote corner of an unimportant room, where it was overlooked or charitably tolerated as "interesting." One misses some of the amenities of the old exhibitions when the larger space of the New Gallery permitted the trade exhibits of apparatus and demonstrations of certain processes. At the Society's house there is inevitably some overcrowding and an almost bewildering wealth of exhibits, although the dealers are limited to advertising pictorially the capabilities of their productions. Photography has always been popular among medical men, partly as a hobby, partly as an opportunity to secure exact records, whether of specimens or cards, or as photo-micrographs, or, in more recent times, on the radiographic side. Some particularly fine specimens are exhibited by Dr. G. H. Rodman, past President of the Society. His photo-micrographs of sections of human muscle affected by trichiniasis show the cysts very clearly in situ and afford an opportunity of seeing what is in this country a rare condition. Dr. G. S. Sansom, who also distinguishes himself on the pictorial side with some excellent transparencies, has some photo-micrographs of embryological subjects. The radiograms of Dr. G. Baer, of Zurich, are instantaneous studies of the duodenum after an opaque meal; they are taken at frequent intervals and so afford a kinematographic demonstration. There are a large number of radiograms from negatives made at various hospitals in Great Britain, but particular attention may be directed to a pair showing the lungs in full inspiration and expiration respectively. Although a certain amount of criticism always attaches to photographic results which are at the same time made semi-diagrammatic, in these examples the diaphragmatic movements, the lighting up of the apices, and the general appearance due to pulmonary expansion are most instructive. Apart from the purely professional side there is much in the exhibition of general interest to appeal to any medical man whatever his tastes and hobbies. The exhibition will remain open until Oct. 25th from 11 A.M. till 9 P.M. daily (Sundays excepted), and it may be added that admission is free.

---

[1] Journal of Mental Science, July, 1924.

AN INFECTION WITH ALL THREE MALARIAL PARASITES.

MALARIAL infections vary greatly in their amenability to treatment by quinine, although opportunity seldom arises to prove this in the history of a single case. Hence the particular interest of a report by Dr. Kadri Mehemmed,[1] a medical officer in the Turkish Army in Asia Minor, on a patient in Cilicia who complained of pain in the abdomen, diarrhœa, and daily attacks of fever, with a long history of malaria. When his blood was examined next day a severe infection with both benign tertian and quartan was found, and a slighter infection with subtertian crescents. Two days later he was put on quinine, 15 gr. daily in four divided doses. Eighty hours later, after the patient had taken 52 gr. in all, no benign parasites at all were observed, but only deformed quartan parasites and crescents. The patient was put on 15 gr. daily for seven days, thereafter on half doses, and after three weeks' treatment only crescents and very few of them were to be seen; the diarrhœa had ceased, and the spleen had become normal in size. The after-history of this case should be interesting, for although in the early stages of infection the benign tertian parasite is the form most easily dealt with by quinine, the successful treatment of a relapsing case is one of the most difficult problems in malaria; relapses are apt to continue in spite of the use of quinine in full doses. Dr. Mehemmed's patient was fortunate if the check to infection was lasting.

MONOGRAPHS OR SYSTEMS OF MEDICINE.

THE multiplication of medical literature and the increase in known facts concerning medical science have in recent years produced a situation which must be full of embarrassment to both donor and recipient, for many special works are available, and the data have become at the same time so unwieldy that even the best of general books is bound to have omitted many important facts. There is evidence that editors to-day shrink from the complexity of attempting to bring out new text-books of medicine, but we have been able in our review columns to welcome several daring and successful ventures in this respect. Dr. E. P. Poulton's revision of "Taylor's Medicine," and Dr. Frederick Price's "System of Medicine," may be quoted as illustrations. But a system of medicine in many volumes is an even more difficult task; it cannot be attempted without the collaboration of many writers, and it is almost inevitable that the work must in some respects be out of date before it reaches the reader's hands. In France this difficulty is to some extent met by issuing finished volumes as soon as each is completed, and it is noteworthy that no less than three different systems, one of which will have when completed more than 30 volumes, are appearing in this manner from Paris. In our review columns to-day will be found an account of a new "System" recently published in the United States; whilst apparently not free from the defects which must occur in any work of these dimensions, this ten-volume series contains many remarkable chapters on different aspects of disease. It has the advantage of being issued in a leather binding with the pages held together by the loose-leaf system, a feature which we believe was first introduced into medical literature in "Oxford Medicine," a six-volume work by various English and American writers which was published by the American branch of the Oxford University Press, under the general editorship of Prof. Christian and Sir James Mackenzie. The new ten-volume work, whose title is "Tice's Practice of Medicine," introduces a further novelty in the form of an annual supplement by which subscribers can each year receive new pages to be incorporated in the text so as to bring it completely up to date.

To possess such works as these is to possess a library; the cost is necessarily great, and would allow the purchaser, for the same expenditure, to buy a series of standard works whose contents might, perhaps, more fully cover the field of medical science. But there is certainly something convenient in the possibility of preserving the subject-matter under a series of uniform covers, and for this reason we believe that the loose-leaf method will enjoy popularity.

PROF. PAVLOV'S SEVENTY-FIFTH BIRTHDAY.

Ivan Petrovitch Pavlov, the great Russian physiologist, attains on Sept. 27th his seventy-fifth birthday, covered with distinctions and international honours. At Leningrad the event will be celebrated by the publication of a *Festschrift* in the form of a special number of the *Archives of Biological Science*, the official organ of the Institute of Experimental Medicine, of which Pavlov is honorary director. Appropriately, we have received from one of Pavlov's former colleagues, Prof. W. N. Boldyreff, who is now Director of the Pavlov Institute of the Battle Creek Sanitarium, U.S.A., an interesting biography of the man who may be said to have raised physiology to the level of an exact science. Prof. Boldyreff divides Pavlov's studies into three groups: investigations on (1) the heart and circulation of the blood; (2) the digestive system; and (3) the physiology of the brain and the organs of sense.

In the first period of his scientific work he studied in detail the innervation of the blood-vessels and of the heart. As a result of this, he brought out a report on the work of the special branches of the vagus nerve. In 1885, and earlier (1877), he published papers on the accommodating mechanism of the blood-vessels. Even at that time he was interested in the physiology of digestion and published some excellent articles on this subject, among them being papers on the nervous mechanism of pancreas juice secretion (1878). During the same period, under the guidance of Ludwig, Pavlov reported studies on the innervation of the left ventricle of the heart and, in collaboration with Heidenhain, he fully investigated the nerve-muscle mechanism of the opening and closing of the operculum of the snail. Early in his scientific career (1879) he described a new method of operation for the pancreas fistula. In 1890 he made his discovery regarding the influence of the vagus nerve upon the process of secretion in the gastric glands. Simultaneously he invented his method for obtaining the gastric juice of dogs, the famous "sham feeding method." The results of these discoveries were so interesting and encouraging that he turned his entire time and interest to the study of the nerve-physiology of the digestive organs, and shortly thereafter he perfected his method of operation for the isolated stomach-pouch. To Pavlov we also owe our knowledge of the influence of the vagus and sympathetic nerves upon the secretion of the pancreas and two excellent methods for demonstrating the mechanism of the action of these nerves. The first method is to excite the sympathetic nerves by mechanical stimulation with the Heidenhain tetano-motor. The second method involves a special operation on the animal by which, with the automatic stimulation of the vagus nerve by the Dubois-Raymond inductorium, the secretion of the pancreas is obtained.

In his preface to the biographical sketch Prof. Boldyreff tells of the hardships Pavlov was forced to undergo as a consequence of the Russian revolution in 1917. The great scientist, he says, who had done so much to relieve the sufferings of others, was himself compelled to suffer want and hunger, and, at an advanced age, to spend the time and energy so valuable to science in manual labour to provide food for his family, in addition to performing the humblest domestic duties and household drudgery. In spite of these efforts, especially in the years 1920 and 1921, he and his family suffered severely from the lack of food due to the bad harvest in Russia. During this time he was helped as well as cheered by the contributions of his scientific colleagues in foreign lands, who made great and persistent efforts to send him aid at a time when such a multitude of eminent Russian scientists and thousands of the common people perished from starvation and disease. In the midst of all his tribulations Prof. Pavlov's courage and fortitude never failed him. He even continued his scientific work in the face of great difficulties; and surrounded by his faithful though hungry pupils, hungry himself, in an unheated building, with water pipes frozen and no light other than that from burning faggots, he encouraged and inspired his assistants by his courageous example in continuing the important scientific work to which his life has been devoted.

BENIGN TUMOURS OF THE PLACENTA.

IN a recent communication to the Chicago Gynecological Society, Dr. R. A. Scott,[1] of the obstetrical service of the Evanston Hospital, Illinois, records an illustrative case, with a review of the literature, of benign tumours of the placenta. Yamato in 1913 collected 116 cases, in addition to which Dr. Scott has found reports of 36 other cases. The first case on record, of which an interesting extract is given, was reported by John Clark in the Philosophical Transactions of the Royal Society in 1798. The tumours are generally found in the midst of the placental tissue in the chorionic membrane, protruding as a rule on the fœtal surface of the placenta. The majority are encapsulated. The tumours consist of sharply defined nodules of lobulated structure, connected with the chorionic epithelium by one or more pedicles and with the rest of the placental tissue in various ways by secondary fibrinous adhesions, lying in the intervillous space and touching neither the chorionic epithelium nor the decidua directly. The tumours are usually solitary, but multiple growths have been observed. The majority of patients are under 30 years of age and primiparous. The health has usually been good before and during pregnancy. There was not a single instance of maternal syphilis in Yamato's series of 116 cases. In size the tumour usually varies from that of a walnut to that of a kidney, but in a few instances the tumour has covered two-thirds of the placental area. It appears to play little part in the pathology of labour. The chief microscopical features are the embryonic connective tissue and the cavernous capillary proliferation. The chorionic epithelium is involved only secondarily in the proliferation, and is an entirely subordinate menace. Dr. Scott's patient was a primigravida aged 32 years. The pregnancy was normal, the urine negative, and the blood pressure 118 mm. Labour took place spontaneously at full term, delivery being effected by low forceps. The placenta was expelled 15 minutes later by the Duncan method. The baby weighed 6 lb. 12½ oz. and was in good condition. Examination of the placenta, which measured 20 by 18 by 3 cm., showed a dark-red firm mass of uniform tissue, measuring 5 by 4·5 by 2·5 cm. and weighing 70 g., situated opposite the attachment of the umbilical cord and in the placental substance. The mass was encapsulated and could be shelled out of its capsule. On microscopic examination multiple blood-vessel spaces of irregular size were seen filled with blood and lined with epithelium. Most of the blood-vessels had thin walls, but occasionally there were groups of large thick-walled vessels resembling arteries. The diagnosis was hæmangioma of the placenta.

THE RECOVERY OF THE VOLUNTARY HOSPITALS.

THERE was a brief period, after the war, when the outlook for the voluntary hospitals of this country seemed dark. The repeated story of accumulated dilapidations, rising salaries, and soaring cost of renewing equipment, depressed even enthusiasts for the voluntary system, and rumour had it that complete recovery was hardly to be looked for. At this stage, when enterprise was constantly being embarrassed and baffled by difficulties, the Government stepped in and offered the sum of £500,000 as a special emergency grant to be administered only to those hospitals which showed a lively disposition to help themselves. The Voluntary Hospitals Commission, who were appointed in 1921 to distribute this sum, were instructed, after the settlement of some urgent claims, to disburse money only pro rata against new money raised or about to be raised by the charity. This stringent condition, which has doubtless led to hardships in individual cases and has been sharply criticised, has justified itself. The second interim report of the Voluntary Hospitals Commission, which has just reached us, leaves no doubt whatever on this point, or that the timely stimulation has brought about a wonderful recuperation if not indeed a cure. It will be remembered that the first interim report of the Commission[1] recording the distribution of £372,000 was published in February, 1923. By March 31st of that year a further £55,000 had been allocated, leaving £73,000 to be used to assist those hospitals with serious accumulated deficits. A sum of £46,000 was allocated to England and Wales and £27,000 to Scotland. Local committees were asked to submit proposals for distributing the sum allocated to their area among the hospitals within it, and they were also urged to raise county funds, in order to facilitate compliance with the Treasury condition as to new money. The supplementary distribution proceeded, with the help of the local committees, until the latter part of 1923, when it was decided that the sum of £16,866 still at the disposal of the Commission should be distributed so far as possible to assist hospitals which were in acute financial difficulties, but for various reasons had been unable to receive an adequate measure of assistance from the Government grant. This final distribution was made easier by a special concession granted by the Treasury. Under an amending regulation the Commission were given a discretion to waive the condition as to new money in exceptionally hard cases, and were able to make grants to a few deserving hospitals which could not otherwise have been assisted. The sum distributed, however, without requiring the equivalent amount of new money to be raised, was only between £6000 and £7000. A complete detailed list of all the grants paid to hospitals is given in appendices. The Commission praise the local voluntary hospital committees, who in most of the areas have assisted in organising and coördinating the raising of funds, and have secured, inter alia, the adoption of a uniform system of accounts. Some of these committees have issued valuable reports[2] in which they have envisaged the hospital needs of their area as a whole and have indicated the possibilities of coöperation between the institutions in the area. Having completed the distribution of the grant, the Commission are now directing their attention, at the request of the Minister of Health, to the need for additional voluntary hospital accommodation and the best means of providing and maintaining it, and not till this investigation is completed, and perhaps not then, will their task be finished. The fact that an inquiry into the provision of more beds seems worth pursuing is sufficient answer to those who are still gloomy about the prospects of maintaining the present quota of voluntary hospital beds. The comment on the present financial position of the hospitals in the final section of this interim report is that "there is substantial ground for the hope that the voluntary hospitals will, for the most part, be able to balance their budgets. They are actively exploring the possibilities of securing additional income and in general the deficits appear to be decreasing. In some instances the recovery has been astonishingly rapid, and the situation as a whole is decidedly more hopeful than we had any reason to anticipate when we began our work. We believe that the recovery of the voluntary hospitals will continue, and that their financial position is approaching a more stable and satisfactory condition." This is a more encouraging statement than anyone could have anticipated in 1921.

MENTAL SERVICES OF THE M.A.B.

THE Mental Services Section of the report of the Metropolitan Asylums Board, summarised on another page, is enriched by a review of work undertaken at Caterham Mental Hospital laboratory, by Dr. J. Leslie Gordon, and by four original articles of unusual merit, notably on the Diagnosis of Mental Deficiency, by Dr. E. B. Sherlock; on Syphilis as an Ætiological Factor in Mongolian Idiocy, by Dr. R. M. Stewart and Dr. D. O. Riddel; on An Application of the Methods of Industrial Psychology to Mentally Defective Persons, by Dr. P. D. McGowan and Dr. John Ross; and on Cases Illustrating the After-effects of Encephalitis Lethargica, by Dr. Charles Glen. In the first of these Dr. Sherlock criticises the well-known "Intelligence" tests, and suggests the application of tests designed to investigate capacity for sensation, memory, and reasoning. He gives examples of questions, ingeniously framed to eliminate guesses, designed to help an examiner to judge the extent to which the defective appreciates time, causal, spatial, and other relations. In some cases the mere ability to understand the question put may supply evidence that the relation involved is appreciated. About the tests there is an illusory appearance of simplicity. For example, the first question under the heading Spatial Relation proposed in the sample scheme is: Draw a straight line and then mark it so that one part shall be twice as long as the other. As originally planned, the wording of this question was "Mark the middle of this line," but this proved so easy for feeble-minded persons that the test given above was substituted. Yet, as shown by H. K. Wolfe, the apparently simple business of marking the middle point of a line raises all sorts of issues in reference to the influence of the age, sex, and experience of the person tested, the length or direction of the line, the variability of error, and so on. Again, though either test will do as a means of detecting the ability to cognize a relation, there has been found little correlation between the "static" form of spatial perception required for the estimation of the lengths of two portions of a line and the "dynamic" form involved in drawing a line of a given length. Actual employment of the tests has brought out unexpected possibilities of error, misunderstanding, novel implication, or legitimate difference of opinion. In order that there might be collected some evidence bearing upon the actual utility of the tests, they have been applied to (1) a group of boys at a preparatory school; (2) groups of higher-grade male and female children at Darenth Training Colony; (3) a group of female nurses; (4) sundry persons casually met with in daily intercourse. The results have been found full of interest and with a considerable measure of value. Dr. Sherlock doubts whether these tests will lend themselves to any process of standardisation on an age basis, but suggests that if the principles underlying them are accepted as sound, they seem likely to be of assistance in arriving at a decision upon the extent of a person's need for "care, supervision and control." They are, at any rate, not purely empirical, but serve for the measurement of a fundamental process of thought, the cognition of relations. We recommend all those interested in the progress of mental hospitals to study this section of the report, which can be obtained separately (price 1s.).

VASECTOMY IN GERMANY.

A SHORT note in the *Deutsche Medizinische Wochenschrift* for August 15th by Dr. Levy-Lenz, under the heading of "Zur Technik der Ambulanten Steinach-Operation," gives the impression that this operation is being performed on a large scale in Germany. Dr. Levy-Lenz speaks of a personal experience of some 50 cases, the use of the word "some" suggesting that a few Steinach operations more or less hardly count. He betrays no great enthusiasm for the results and admits that he has seen no improvement when the operation has been performed for normal old age. But when old age has been premature and has been associated with slight mental depression, he has known the operation to be beneficial. As for the observations of other surgeons, he finds that opinions differ widely. This, he thinks, may be because some surgeons have been more discriminating than others in their choice of patients. But the most striking feature of Dr. Levy-Lenz's note is his description of the ease, facility, and rapidity with which vaso-ligature, according to Steinach's technique, is now being performed in Germany. It seems to have become an out-patient or consulting-room incident. The operation, we are told, is perfectly free from danger at the time and also from unpleasant sequels. All that is needed for it are scissors, a knife, two surgical forceps, a stout probe, silk, a needle, a one-tooth hook forceps, and a local anæsthesia outfit. The vas is gripped through the skin of the scrotum as near to the testicle as possible, is isolated from the other constituents of the cord, and is secured in a longitudinal fold of the skin. The skin is disinfected, the local anæsthetic is injected, and a 2 cm. long incision is made over the vas, which is laid bare and pulled forward with the help of the probe. It is then ligatured at two points with silk and divided. The wound in the skin is closed, a small dressing is applied, and a suspensory bandage is worn for 14 days. Dr. Levy-Lenz says that the whole operation takes from five to ten minutes, but that, apart from a transitory "flare-up," results should not be expected till four to six months after the operation.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

A. L. McDonnell to be Surg. Lieut.

Surg. Capt. R. W. G. Stewart to *President*, for post-graduate course.

Surg. Comdrs.: E. S. Wilkinson to *Ramillies*; G. B. Scott to *Resolution*; W. W. Keir and H. St. C. Colson to *President*, for survey of medical stores at R.N. Medical Depôt, Deptford; D. H. C. Given to *President*, for post-graduate course; G. B. Cockrem to *Despatch*; and R. Thompson to *Marlborough*.

Surg. Lts.: W. J. McB. Allan to *Ramillies*; S. G. Weldon to *Marlborough*; and Surg. Lt. (D.) H. J. Luck to *Malaya*.

Surg. Lt.-Comdrs.: A. W. Gunn to *Centurion*; P. W. Carruthers to *Impregnable*; and I. S. Gabe to *Fisgard*.

C. C. Grummitt has been appointed Admiralty Surgeon and Agent for Hove, in addition to Brighton.

ROYAL ARMY MEDICAL CORPS.

Capt. Alexander S. Newton to be temp. Capt. whilst empld. as a Dental Surg.

ARMY RESERVE OF OFFICERS.

Lt.-Col. H. A. Harbison ceases to belong to the Res. of Off. on account of physical unfitness.

TERRITORIAL ARMY.

C. Alison (late R.A.M.C.) to be Lt.

INDIAN MEDICAL SERVICE.

The King has approved the retirement of Lt.-Col. W. H. Kenrick.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

LXXXVIII.

TREATMENT OF EPIDEMIC ENCEPHALITIS (ENCEPHALITIS LETHARGICA).

THE early diagnosis of epidemic encephalitis is of importance, not because there is a specific treatment as in diphtheria, which must be given early to be effective, but because some of the conditions which simulate it, such as intracranial tumour or abscess, cerebro-spinal fever, cerebral syphilis, uræmia, and various drug poisons, call for quite other treatment, the delay or omission of which may be of serious import. Conversely also, some cases of encephalitis may easily be mistaken for other conditions. Painful abdominal myoclonus has been diagnosed as an acute emergency, and laparotomy performed in consequence; whilst the curious moral changes of behaviour, which so often occur in children as the result of this infection, have in some instances been dealt with as wilful naughtiness with most unhappy results. A definite diagnosis cannot, however, be made until characteristic nervous signs show themselves. Early or premonitory general symptoms may be present in some cases for days, in others for weeks, but there is nothing distinctive either in their character or in their grouping. Thus by the time that its presence is recognisable the poison has already reached the nervous system.

Disinfection.—It is believed that the primary site of infection is the mucous membrane of the mouth and naso-pharynx. Measures may therefore be taken to disinfect these regions from the first. Potassium permanganate solution (1/1000) was found by Levaditi to be particularly effective in destroying his virus under experimental conditions, and there is thus some justification for preferring it for this purpose.

Rest.—Rest in bed is clearly indicated in severe cases, and in them not difficult to enforce, but it is sometimes not easy to persuade a patient suffering from nothing but a slight diplopia to remain in bed for some days. However, the mildest case may at any moment develop into one of serious character. Many fatal cases have for varying periods seemed to be exceedingly mild. Whether any of these would have run a less serious course had they been kept in bed from the first it is not possible to say, but it seems reasonable to insist that any person suffering from an acute infection of the central nervous system should be kept in bed at any rate until the acute stage may be assumed to be over, however slight that infection may appear to be.

Isolation.—The question of isolation is one of considerable difficulty, seeing that instances of direct infection are extremely rare. Theoretically no doubt it is desirable, but practically it is impossible to carry out a complete scheme of isolation based upon our scanty knowledge as to the conditions of transmission, or the period of infectivity. General measures as regards the hygiene of the sick-room should be adopted. At the Sheffield City Fever Hospital, where large numbers of cases have been under treatment during the recent outbreak, those kept out in the open all day appear to have been less excitable and to sleep better.

Diet.—Food should be light and palatable. In the acute restless cases the difficulty of feeding is often as great as in severe cases of chorea, and it is important to make sure that adequate quantities are taken. Some of these cases lose flesh rapidly. The same applies to the very lethargic patients, who will go for hours together without food unless made to take it. Dysphagia from bulbar lesions may add to the difficulties in some cases; it is usually only temporary.

Management of a Case.

Many lines of treatment of the infection itself have from time to time been suggested. Amongst these are the fixation abscess, "pure influenza" antigen, serum from convalescent cases, sodium salicylate intravenously (administered in 1/30 solution, 1 to 3 g. daily). Individual observers have praised these and other remedies, but none has received general support, whilst some have been definitely abandoned by those who previously advocated their use. At the present time various workers in Paris are testing the value of intra-thecal injections of a vaccine prepared from the central nervous system of rabbits infected by the virus which Levaditi obtained from the brain of a human case. The results are said to be encouraging, but they are still too few and uncertain to warrant undue optimism. In some of the cases so treated an undesirable meningeal reaction has occurred, and it seems doubtful whether repeated lumbar puncture in this disease may not itself be actually harmful. Some believe that it should be avoided if possible, and never performed in cases where the diagnosis is obvious; others, however, consider it is of therapeutic value in the relief of lethargy and other symptoms. Probably the most generally used drug, on theoretical grounds, is hexamine, given in full doses (10 gr. t.d.s.) over considerable periods, during which the urine should be examined daily for signs of irritation of the kidneys.

In the acute restless cases, with choreiform movements, careful nursing is essential. It is important to protect all parts liable to be chafed by the patient in his violent movements, since otherwise intractable sores may be produced on the elbows, knees, ankles, and elsewhere, even in a single night. Patients may at any time become extremely violent, and assistance should always be readily available. In some cases the use of a restraining sheet may be necessary. Sponging, ice-bags, or cold affusions to the head may be tried, the last-named being the most effective. (Tepid, cold, or even iced water is freely sponged over the head, face, and neck for about ten minutes every four hours. In males the hair should always be cut quite close; in females, only in very severe cases.) Sedatives in full doses are usually required. Bromides and chloral hydrate or chloretone, used alternately, have proved the most generally useful. If these fail, recourse must be had to an injection of hyoscine hydrobromide (gr. 1/200 to 1/100), which usually gives temporary relief. As a rule, this acute stage, if not fatal, diminishes in severity in a few days, sometimes with remarkable suddenness and independently of any particular treatment; this is a point to be borne in mind in assessing therapeutic values. In a few cases the maniacal symptoms may call for removal to a mental hospital in the interests of the patient.

Intense neuralgic pains in the head or elsewhere may occur at onset, and persist with extreme severity in spite of treatment. Drugs, such as antipyrin, phenacetin, aspirin, butyl chloral, gelsemium, bromides, &c., upon which reliance is usually placed in similar circumstances, often fail to produce any effect in these cases, and opium, in the form of Dover's powder, or morphine may be required from time to time. Myoclonic spasm may be extremely painful, and lead to great exhaustion and distress. Local pressure by pads and bandages, hot fomentations, and anodyne liniments are usually of little avail. Emplastrum sinapis applied to the epigastrium is occasionally useful. In severe cases morphine is required. The administration of an anæsthetic has at times been the only means of giving temporary relief. One or two observers claim success with injections of 10 c.cm. of the patient's own spinal fluid, but it must not be forgotten that the abdominal spasms which cause such acute pain when they first appear usually cease to be so painful after a few days, and that gradually the spasms may occur almost painlessly.

For the attacks of disordered breathing (polypnœa, dyspnœa, &c.), which often cause considerable alarm when they first occur, oxygen may be administered with good effect. In most cases a confident assurance to the patient and his friends that they are not dangerous and a simple sedative will suffice.

In the acute stage troublesome constipation often requires attention; frequent soap-and-water enemata may be useful. The tongue may remain foul and coated for longer than the general condition appears to warrant, when ordinary methods of local cleansing should be employed.

After-Treatment.

After-treatment may demand great patience and endurance. When once the acute stage is over, say in two to four weeks, there does not seem to be any necessity for complete rest in bed. Many cases remain weak both mentally and physically for very long periods, and require a long rest before returning to work. A sea voyage, a holiday abroad, a quiet retreat in the country, at the sea, or even at home, whatever course is decided on, must be designed as a real rest for the mind, and must therefore be congenial to the patient. In some cases motoring has proved effective.

The *Parkinsonian syndrome* as a sequela presents great difficulty in treatment. Massage, hydrotherapy, and passive movements have been advocated, and in some cases give a certain amount of relief. Electrical applications appear to give no benefit, and in some cases to do harm. Various drugs have been recommended, including arsenic, luminal, belladonna, and tincture of arnica. Scopolamine undoubtedly relieves the tremor and rigidity for a time, but has no permanent effect. Its use cannot be continued for long periods. After choreiform attacks recovery may be considerably hastened by the judicious employment of regulated exercises. For this purpose simple callisthenic arm exercises may be carried out, or, in small children, building with toy bricks. At the City Fever Hospital, Sheffield, Dr. Egerton Williams has obtained rapid improvement in older children by getting them to knit.

The most disturbing sequela is perhaps the peculiar nocturnal excitement and insomnia, which, though not limited to children, reaches its highest grade in them. In most cases much may be done by judicious control and "good mothering." Even then sedatives are often required as well. Of these, bromide and chloral hydrate, or chloretone seem to be the most generally useful. The method of injecting small quantities of milk intramuscularly, which was first suggested by Lust of Karlsruhe, has proved effective in many of our cases; 2 c.cm. of boiled milk are thus given at bedtime, and the child usually goes to sleep in an hour or two, and sleeps soundly for six or seven hours or more. Nor is its action limited to children. In the case of a man who had not been able to sleep until 3 or 4 o'clock in the morning since his acute attack five months ago, intramuscular injections of milk given at 9 o'clock each night for a week produced sound sleep from 10 till 5 next morning. Preliminary injections of distilled water in similar quantity at the same hour had failed to have any effect. It does not always succeed, but should be tried in any obstinate case. In some cases a change to the seaside or country, with plenty of exercise in the fresh air, will give temporary relief, but a relapse on returning to home conditions is not uncommon.

ARTHUR J. HALL, M.D. Camb., F.R.C.P. Lond.,
Professor of Medicine, University of Sheffield;
Senior Physician, Sheffield Royal Hospital.

Special Articles.

THE RESPONSIBILITIES OF THE M.A.B.

THE annual report[1] of the Metropolitan Asylums Board contains, as usual, a historical summary of the evolution of this great organisation and a clear account of the manifold duties it performs for the 28 parishes and unions which make up the Metropolitan Asylums district. To maintain this service, ratepayers at Hampstead combine with residents in unfashionable Wandsworth; Kensington in the West gets as efficient but no better service than does Limehouse in the East.

The Board is composed of 73 members, 55 being elected by the metropolitan boards of guardians and 18 being nominated by the Ministry of Health. Their duties include the provision and management of hospitals and other institutions for infectious diseases, tuberculosis, children suffering from specified contagious diseases and those requiring special treatment in general hospitals or convalescent homes, mental defectives and epileptics, training boys for sea service, and for casual poor; they also provide ambulance and transport services.

Of these activities the fever hospitals and the ambulance and transport service are best known to practitioners as being available for use by the public apart from Poor-law cases, but it is not generally realised how numerous are the contingencies affecting the public which the Board now has to meet. A list given in Appendix III. of the report divides the several classes of persons for whom the Board is now required to provide accommodation into (*a*) the mentally afflicted and epileptics, (*b*) the physically afflicted, (*c*) healthy classes, and this method of classification shows how wide are their responsibilities.

The Mentally Afflicted.

Harmless Poor-law imbeciles of any age, whether regarded as capable or incapable of improvement, have had to be provided for since the inception of the Board in 1867. Since this date also suitable cases certified under the Lunacy Acts transferred from the London County mental hospitals have been received. In 1897 the Board assumed charge of feeble-minded Poor-law children (uncertified), and in 1910 of sane epileptics (Poor-law). From 1917 cases certified under the Mental Deficiency Act, 1913, have been accepted.

It will be seen that during the last 50 years, by formal addition of new classes of persons and, perhaps, still more through freedom in the interpretation of the terms in which the original classes were defined, it has come about that the Board's purview of mental infirmity has extended so as to embrace a wide range of persons. No attempt is made to define the type of lunatic who may properly be detained in the mental hospitals provided by the Metropolitan Asylums Board, which by the Lunacy Act, 1890, are included under the definition of a workhouse.

In practice the Metropolitan Asylums Board now provides in its mental hospitals for: (*a*) Chronic and harmless cases of all forms of insanity; (*b*) idiots and imbeciles who come within the terms of the Lunacy Acts; (*c*) feeble-minded persons as approved by the Local Government Board in 1897 and 1911; (*d*) cases covered by the Mental Deficiency Act, 1913, with certain restrictions.

The distribution of the 9077 beds provided is as follows: Caterham Mental Hospital, 2109; Fountain Mental Hospital, 658; Leavesden Mental Hospital, 2209; Tooting Bec Mental Hospital, 1098; Darenth Training Colony, 2208; Edmonton Epileptic Colony, 355; Brentwood Institution, 350.

At the present time a scheme exists which aims at ensuring the classification of the different types of cases in suitable institutions and the regular movement through the institutions of patients according to changes in age and mental or physical condition,

---

[1] Office of the Board, Victoria Embankment, London, E.C.4. Price 5s.

Thus, at the Fountain Mental Hospital are received all children under 7, unimprovable boys up to 9 years of age, and girls up to 16. The children under 7 are watched and classified so that when the time comes those who are thought to be trainable can be sent on to Darenth Training Colony. A few adult female working patients are maintained at the Fountain Mental Hospital. Tooting Bec Mental Hospital is the receiving home for all adult Lunacy Act cases sent by metropolitan boards of guardians, but no cases under the Mental Deficiency Act are received there. Aged patients are retained at Tooting Bec Mental Hospital. but younger ones. after observation. are transferred to the institutions for which they are suitable. Caterham Mental Hospital receives healthy unimprovable adults of both sexes and a certain number of low-grade trainable cases not up to standard for Darenth Training Colony. Caterham also has a large number of children's beds for unimprovable and low-grade trainable children. receiving the untrainable boys over 9 as they leave the Fountain Mental Hospital. Leavesden Mental Hospital may be regarded as an infirmary institution. It accommodates unimprovable adults of both sexes, chiefly those suffering from chronic infirmity not primarily due to old age.

The full statistical tables given of the work done in the mental hospitals present no features of special importance. Dr. G. B. Sherlock. chief medical officer of the Mental Hospitals Service. draws attention to the curious fact that among the 423 deaths recorded in patients who died at the ages of 45 and upwards during 1923. there were only 15 deaths attributed to cancer—i.e., 3·54 per cent. This is not a new feature, since the corresponding figures for the previous four years were 9, 7, 16. and 21 deaths from cancer. the total deaths being respectively 629. 472, 536, and 557. Dr. Sherlock points out that since most of the patients belong to London. a comparison with the Registrar-General's returns for that area is permissible. For 1923 the numbers were: Deaths from cancer (45 years and upwards), 5535; total deaths (45 years and upwards), 33.056, or 16·74 per cent. The reason for this marked difference between the figures for London and those for the Board's mental hospitals is not obvious.

The Physically Afflicted.

Infectious and Contagious Diseases.—The Board have 14 hospitals for infectious diseases, where they provide accommodation for cases of scarlet. enteric, or typhus fever, diphtheria. measles. whooping-cough. puerperal fever. cerebro-spinal fever, ophthalmia neonatorum. trench fever. malaria, and dysentery. All patients suffering from these maladies. whatever their status, are now receivable. Poor-law children suffering from ophthalmia or other contagious diseases of the eye are treated in an institution (White Oak, Swanley) which is a collection of groups of similar cottages. and serves the double purpose of hospital and school. There is room for 360 children, and Mr. E. Treacher Collins acts as visiting ophthalmic surgeon. During 1923 271 children were discharged cured. 240 were admitted; 101 from metropolitan and 22 from extra-metropolitan Poor-law schools, and 117 from London County Council schools. Apparently these are the only sources of admission, and since the reduction in the number of cases leaves vacant accommodation at this hospital, now partially used as a convalescent home. we suggest that the admission of patients from middle-class homes who attend private schools might be worth consideration by the Board. on the analogy of the reception of patients of this class into fever hospitals. Diseases of the skin or scalp in Poor-law children are treated at Goldie Leigh Homes, Abbey Wood: during the year 591 children were dealt with, the large majority suffering from ringworm, and here also the admission of the public other than those coming under the Poor-law might be greatly appreciated. A detailed account of the methods used at this home. giving a proportion of 487 cures out of 513 cases of ringworm. would be of interest. The Infectious Diseases section of the report, taking up 81 pages, is edited by Dr. F. Foord Caiger, chief medical officer of the infectious hospitals service, who besides contributing a note on the protective inoculation by the Schick test and active immunisation against diphtheria of the boys on the training ship *Exmouth*, makes observations on certain of the statistical tables. He calls attention to the lower incidence of scarlet fever and of diphtheria in London. and to the diminution of the death-rate of these diseases from 1·8 per cent. and 8·7 per cent. respectively in 1922 to 1·2 per cent. (scarlet fever) and 6·8 per cent. (diphtheria) in 1923. The last-named figure is still considered too high and could be materially reduced by the earlier administration of antitoxin. Incidentally in a note on the death-rate in diphtheria as influenced by the dosage of antitoxin. which forms one of 16 noteworthy contributions by medical officers to this section of the report. Dr. Margaret Björkegren observes that in so far as inference can be drawn from statistics in so complex a subject. the average optimum dose would seem to be about 20.000 units per patient. Dr. Caiger points out that the incidence of enteric fever is now so small that the disease has been omitted from the charts.

Owing to the low prevalence of scarlet fever it has been possible to devote more beds to the reception of measles and whooping-cough. 1767 cases of measles were admitted during the year with the very low case mortality of 7·7. The whooping-cough mortality, on the other hand, was high—14·6 per cent. of 528 cases admitted. The puerperal fever admissions during the year numbered 78, of whom 15 died. Sir Almroth Wright and his assistants are making trial of the immuno-transfusion[2] treatment on certain of the more severe cases of septic infections in three of the fever hospitals in coöperation with the medical officers, but the number of cases so treated is not yet sufficiently large to pronounce on its value.

Cases of mistaken diagnosis, that is to say, cases of diseases properly admissible into the fever hospitals in which, either at the time of their reception at the hospital. or as the result of subsequent observation, the diagnosis of the certifying practitioner was not confirmed, numbered 3527. The disease in respect of which a mistake in the diagnosis was most common was. as usual, enteric fever. The diagnosis of enteric fever was negatived in no less than 37·9 per cent. of cases so certified, the diseases most often mistaken for enteric fever being pyrexia of unknown origin, pneumonia. enteritis, influenza, and meningitis. Diphtheria comes next with 20·9 per cent. (the figure for 1922 was 14·1), mistakes being most frequent in respect of tonsillitis, laryngitis, and Vincent's angina.

Research into problems connected with scarlet fever is being actively pursued in the Belmont Laboratories by the research pathologist to the Board, Dr. W. Mair, who contributes to this report an article on the ætiology of scarlet fever.

Tuberculosis.—The section of the report devoted to tuberculosis deals with the arrangements made for cases (*a*) of pulmonary tuberculosis, (*b*) of non-pulmonary tuberculosis. The Board has entered into arrangements with the London County Council under which they provide residential treatment for tuberculous patients in the County of London. The institutions for adult patients under their control include two sanatoriums for early cases of pulmonary tuberculosis, three hospitals for advanced cases, and one hospital for surgical tuberculosis. For children suffering from tuberculosis three institutions have been provided—two at the seaside and one in the country. Provision has been made in all for 1000 adults and about 1200 children.

Dr. James Watt, the chief medical officer of the Medical Tuberculosis Service, commenting on the statistics for pulmonary tuberculosis, pleads for more beds for advanced cases, since continued voluntary segregation would, in his opinion, do much to prevent the spread of infection. With regard to the ultimate result of treatment, as measured by the proportion of cases surviving four to five years after discharge from the sanatorium, Dr. Watt states that a misleading impression has been fostered that in general all the negative cases do well and all the positive cases do badly. The statistics of the London County Council show that only about 30 per cent. of the positive cases survive for four to five years, while about 70 per cent. of the negative class are alive at the end of that period. But it is clear from the figures given that although the prognosis is good where the lung lesion is slight, and there is not much deterioration of the general health, yet even in the negative class, where the lesion is extensive and the general health considerably affected, the issue hangs in the balance. There is a good case therefore for giving as thorough and as prolonged treatment to patients of the negative as of the positive class. A certain proportion of the former are so little deranged in health that a short period of treatment and education may suffice; but on the other hand a considerable proportion of the positive class have so little prospect of recovery, even with prolonged sanatorium treatment, that the latter is wasted on them, and could be replaced by less expensive methods of teaching the rules of healthy living.

---

[2] See THE LANCET, 1923, ii., 1341.

The section of the report devoted to non-pulmonary tuberculosis, which service is under the general direction of Dr. W. T. Gordon Pugh, includes a description of Princess Mary's Hospital for Children at Margate, which has 271 beds and excellent educational facilities. Six signed articles on special points by medical officers of the tuberculosis service of the Board are appended.

Other Diseases.—Poor-law children requiring seaside air or special treatment in a hospital or convalescent home are well served. Queen Mary's Hospital, Carshalton (900 beds), and The Downs Hospital, Sutton (360 beds), take all sorts of cases. St. Anne's Home, Herne Bay, provides 15 beds at a seaside convalescent home, supplemented by beds at White Oak, Swanley.

The section of the report dealing with children includes a lengthy and copiously illustrated monograph on the Conservative Mastoid Operation and its Objects, by Mr. Charles J. Heath, consulting aural surgeon to the Downs Hospital for Children.

Venereal Diseases.—The treatment of venereal diseases at the Sheffield-street Hospital has been continued during the year; 121 women, 7 of whom had babies with them, were admitted to the hospital, while 21 babies were born in hospital. At the Thavies Inn Institution for parturient women suffering from venereal diseases, Mr. John Adams records a diminution in the number of cases of syphilis and believes that this decrease is likely to continue. During the year under review 12 mothers were admitted with syphilis, 10 infants were born alive, 6 with positive and 4 with negative W.R. As to the two stillborn fœtuses, one mother was admitted in labour and the other was confined seven days after admission, neither having had previous treatment. At St. Margaret's Hospital for ophthalmia neonatorum, where mothers may be admitted with infants, 164 women and 225 infants were admitted during the year. Dr. Doris M. Howard records that 203 infants were discharged with sight unimpaired, 19 with sight impaired in one or both eyes, and 3 blind in one eye. The hospital now undertakes the treatment of venereal disease in the mothers admitted with their babies, with good results. This hospital is not confined to Poor-law cases.

Healthy Classes.

Since 1875 the Board have received Poor-law boys for training for sea service (including many received from extra-metropolitan parishes and unions), and since 1911 they have had to deal with the "casual poor." The number of boys admitted to the training ship *Exmouth* during the year was 290. Of the boys discharged, 45 entered the Royal Navy, 153 the Mercantile Marine, and 21 were drafted into the Army as musicians. With a view to increasing the physical standards of the boys, the dietary scale on the ship has been improved by the addition of more milk and the introduction of greater variety in farinaceous foods and dried fruits. The question of a further revision of the scale is under consideration. As to the casual wards, one of the seven in use during 1922 has been closed and used as a hostel for men, carefully selected from the casual wards or from the night office, who are likely to find work.

The length of stay in the hostel is ordinarily limited to 14 days. The inmates are given a more liberal diet than is provided in the casual ward; are subject only to such regulations as are necessary for the proper conduct of the institution; and are allowed complete liberty to seek work, with the result that many situations have been found by the men. The likelihood of response to the assistance which they would be given was the sole factor in the selection of the cases, as is illustrated by the fact that the men were drawn from over 70 trades. Of the 471 cases admitted to the hostel during the first six months, 130 were known to have found employment, of whom only 15 subsequently returned to the casual wards.

The Board has approved the continuation of this apparently excellent scheme for the full period of one year for which it has been sanctioned by the Ministry of Health.

THE MILK PROBLEM AND THE MINISTRY OF HEALTH.*

The fresh milk consumed in this country is for all practical purposes entirely home produced, in this respect differing from all our other food-supplies. There are over 2½ million dairy cattle in the country, and of these nearly 2 million are actually producing milk. The yield of milk during 1923 was 1150 million gallons, and of this the amount consumed as fresh milk was 730 million gallons. When it is remembered that some 2 per cent. of the milking cows are yielding milk containing tubercle bacilli; that much of the milk distributed for consumption as such is produced under extremely unhygienic conditions and is liable in course of production, handling, and distribution to gross contamination by dirt derived from varied sources; that such milk may be consumed by young infants, delicate children, and invalids; and that even where milk is treated by heat the process employed is rarely capable of destroying disease-producing organisms, it is abundantly clear that there exists a formidable milk problem bearing directly on the health of the community.

Importance of Milk as a Food.

In view of the great value of milk as a staple article of food, especially for the young, Sir George Newman unhesitatingly lays down that the consumption of milk ought to be much greater than it is at present. It has been estimated that the average consumption per head of our population per day amounts to no more than a quarter of a pint. This is less than half the quantity consumed in most other countries, notably in America, and it indicates that there must be a grave deficiency in the amount of milk at present consumed during the early years of their lives by the bulk of the children in this country.

The milk problem as it stands to-day presents two aspects. First, the consumer must be protected as far as possible from risk of infection by disease, especially tuberculosis, and his milk must have a satisfactory, unadulterated, nutritive value; and second, in order to increase consumption, it is necessary that milk should be attractive and appetising, of good keeping qualities, and of recognised economic value. The question of protecting the consumer resolves itself into eliminating tuberculosis from the milking herd and in protecting the milk from contamination by human and other infections, and to this end the Milk and Dairies (Consolidation) Act is designed, in conjunction with the Tuberculosis Order. As a second line of defence stands the Food and Drugs Act, and finally the pasteurisation of milk. The key to ensuring good keeping qualities in milk lies in its efficient handling from the cow to the consumer.[1]

---

* Abridged from a section of the Annual Report of the Chief Medical Officer of the Ministry of Health for 1923. London: H.M. Stationery Office.

A supplementary method of raising the standard quality of milk and of educating both the producer and the consumer has been introduced in the new method of *grading* higher quality milk to be sold under special designations. The system has been introduced and maintained mainly to afford a working example of how milk can be made reasonably safe and attractive. It has had notable success in this respect, and is the parent of a growing movement amongst farmers for improving their methods. Nearly every county in England is now organising "clean milk competitions" on the basis of the Ministry's grading requirements, and the indirect educational value is unquestioned. The value of a bacteriological standard as a means of judging of the purity of milk has for many years been demonstrated in the United States, and although the method has been employed in practice in this country only during the past three or four years and on the very small scale provided by the graded milks, it has, however, sufficed to initiate a movement in the desired direction, and already the influence of and appeal to the bacterial standard shows evidence of extending far beyond the limited field at present covered by graded milks. But direct education of public opinion is also necessary. A wealthy and influential organisation representative of the trade, agricultural and public health interests, the Milk Publicity Council, already exists. Its objects are to bring about an increase in the demand for milk. It advocates the provision of a good and acceptable article as the essential basis of the success of its aims. It realises that the consumer has hitherto been suspicious of, and dissatisfied with, the quality of the supply. Ordinary milk is suspected of being a cause of disease, and its frequent premature souring is a source of loss and annoyance. In consequence condensed and dried milk, although much more expensive, have been largely substituted. It should only be a matter of time and the development of some decided interest on the part of the consuming public, says Sir George Newman, before definite standards of cleanliness and purity can be insisted on for the whole of the milk-supply.

General Methods of Milk Control.

When opportunity offered the medical officers and milk inspectors of the Ministry have made inquiries into matters relating to general milk production and have conferred with medical officers of health and sanitary inspectors on questions of local administration of regulations to ensure a clean and wholesome milk-supply made under the Dairies, Cowsheds and Milk-Shops Orders. As a result it was found that there was much scope for improvement in the quality and uniformity of administration of these regulations by local authorities in all parts of the country, and, as Sir George Newman states, it is idle to complain of the milk-supply if authorities neglect to exercise the powers they possess.

Sources of Contamination.—The chief sources of contamination are the udder and teats of the cow itself, the hands of the milker, the air, and the utensils and vessels in which the milk is collected and transported, and the principles underlying the maintenance of cleanliness are extremely simple. The regulations include the cleansing of milk vessels by steam or clean boiling water, the cleanliness of the udder and teats of the cows, and the thorough cleansing of the hands of the milkers. With the addition of adequate cooling it would be quite possible for the producer to comply with any ordinary bacterial standard which is likely to be set up for determining cleanliness in milk.

The System of Inspection.—Enforcement of those sections of the regulations dealing with cleanliness of procedure can only be secured by a well-planned system of inspection, which would include admonitory notification, followed by legal proceedings under the regulations where the failure complained of was continued. Useful work on these lines is being carried out by some local authorities, principally in urban districts. In many of the rural districts, however, owing to largeness of the areas concerned, inadequacy of the sanitary staff and indifference to such matters on the part of local councils, little or no control of any kind is exercised over the production of milk. In consequence there is a growing tendency of the larger urban centres to seek means for their own protection in regard to milk-supplies. In the United States this is the method invariably employed by the larger cities. Inspection of farms for this purpose by the city inspectors involves long journeys over wide areas. The need for such journeys is in many cases reduced considerably as a consequence of establishing a bacterial standard of purity for milk coming into the city.

The proper use of existing powers under the regulations would be strongly reinforced in this respect by the prospect for the producer: (*a*) of obtaining a better price for a better article, or (*b*) by the need for him to comply with a bacteriological standard. At the present time much of the milk collected from adjacent farms at country depôts for conveyance by the large distributing companies to urban centres is so grossly contaminated at the farm that immediately on its arrival at the depôt, often while it is still warm from the cow, it has to be put through a process of "cleaning" (i.e., straining or centrifuging), followed by pasteurisation and cooling, before it can with safety be despatched by rail to its destination. This elaborate attempt to remove from milk, dirt, which the simplest precautions taken by the producer would have excluded, adds considerably to the cost of distribution. Yet the careful producer, whose milk calls for no such treatment, seldom finds himself better off as regards the price he receives for his product than one whose milk cannot be trusted to remain sweet for a few hours without this costly special treatment. There is obviously scope here for adjustment by the trade which could not fail to benefit producers, distributors, and consumers alike.

Milk Grading.

The Milk (Special Designations) Order, 1923, came into operation during the year. The Order was designed to place on a permanent footing the system of milk grading which was developed during the war and carried out for some years under temporary orders derived from war emergency legislation. The new Order, made under the Milk and Dairies (Amendment) Act, 1922, enlarges somewhat the previously existing scheme of grading by adding a new grade in which the tuberculin test for cattle is not required, and by reserving for the term "pasteurised" as applied to milk the significance of a special process carried out under prescribed conditions. The various grades now established by the Order may be summarised as follows:—

1. *Certified Milk* must be produced from cows which have passed a prescribed tuberculin test and veterinary examination. The whole herd must be submitted to the test and veterinary examination at intervals of six months, and every animal added to the herd must be tested immediately before admission. The milk must be bottled on the farm and must not at any time contain more than 30,000 organisms per c.cm. or any coliform organisms in 0·1 c.cm.

2. *Grade A (Tuberculin Tested) Milk* is subject to the same conditions as certified milk as regards the testing and examination of cattle. The milk must be bottled before distribution and must not at any time contain more than 200,000 organisms per c.cm. or any coliform organisms in 0·01 c.cm.

3. *Grade A Milk* must satisfy the same conditions as Grade A (Tuberculin Tested) Milk, with the exception that the tuberculin test is not required and that veterinary examinations of the cows in the herd are made at intervals of three months instead of six months.

4. *Pasteurised Milk* is milk which has been pasteurised by the holder process as defined in the Order—i.e., it must be held at a temperature of 145° to 150° F. for at least half an hour and then cooled to 55° F. It must not be heated more than once and it must not contain more than 100,000

---

[1] Cf. THE LANCET, August 16th, 1924, p. 330.

organisms per c.cm. If the milk so treated is Grade A milk the number of organisms must not exceed 30,000 per c.cm. and there must be no coliform organisms in 0·1 c.cm. Pasteurisation or heating of Certified or Grade A (Tuberculin Tested) Milk is not allowed.

The number of licensed producers controlled directly by the Ministry at the end of 1923 was 101, an increase of 60 per cent. on the number holding licences at the end of the previous year. During the year 14 new licences for the production of Certified and 24 for Grade A (Tuberculin Tested) were issued, and none was revoked on account of failure to comply with the Order.

Visits by the Ministry's milk inspectors were made to all farms in respect of which licences had been issued directly from the department, and each farm was inspected, on an average, once every six months. Before a new licence is issued the farm of each applicant is inspected and a report made on the special score card which has been adopted by the department. This includes a survey of equipment, methods of production, identification of animals in the herd and checking records of the herd, and of the production and sale of milk.

Records kept in the department indicate that at the end of 1923 approximately 4000 animals were included in those licensed herds for which a tuberculin test is prescribed by the Order (2200 on "Certified" farms and 1800 on "Grade A (Tuberculin Tested)" farms). The milk of these grades produced during the year amounted approximately to 6000 gallons daily.

Bacteriological Examination.

Samples of milk taken for this purpose are now in all cases obtained by officers of the various local authorities in whose districts the milk is sold and are despatched by them to the bacteriological laboratory with which the local authority, with the approval of the Ministry, has arranged for the examination of these samples. The reports indicate in general a very high standard of achievement on the part of the producers concerned. In 1923, 83·4 per cent. of the samples examined were within the limits prescribed by the Order, compared with 76 per cent. in 1922, 71·8 per cent. in 1921, and 69·7 per cent. in 1920. Copies of the bacteriologist's report are in all cases sent to the producer, his attention being drawn, where necessary, to any departure from the prescribed limits. Where such has occurred a second sample is taken shortly afterwards, and if necessary a third. It is seldom, however, that the cause of failure has not been removed by the time a second sample is taken. The disclosure which the bacteriological method of control inevitably makes of failure to observe any of the essential details of clean milk production, as well as the general accuracy and fairness of the method are understood and appreciated by producers and others engaged in the trade.

Under the new Order the conditions required in connexion with the tuberculin testing of licensed herds have been revised in some particulars. These include re-tests at six-monthly intervals by the combined subcutaneous and ophthalmic methods and involve the taking of two additional pre-inoculation temperatures and one additional post-inoculation temperature at the sixth hour. These modifications were made on the recommendation of the Tuberculin Committee of the Medical Research Council, whose earlier work in the investigation of this test as applied to cattle strongly indicated the desirability of adopting these modifications. The work of this Committee has continued throughout the year, and the department is indebted to its members and especially to its chairman, Captain S. R. Douglas, for much very helpful coöperation in dealing with the many problems which have arisen in connexion with the application of the tests. It is hoped that the ultimate outcome of the Tuberculin Committee's work will be to simplify and standardise these tests and at the same time enhance their reliability and value as a diagnostic method.

The sale of stock advertised as having passed the tuberculin test appears to be on the increase. The tests in question have not always been carried out in accordance with the requirements of the Order, and licensed producers buying such animals at auction sales have been faced with the difficulty that the certificates are not accepted by the Ministry. Before adding such animals to the licensed herds licensees have been obliged to submit them to a special test which has been devised to meet such cases, but this involves additional expense, trouble, and loss of time to the producer, and it would obviously be desirable in the interests of all concerned if the Ministry's requirements in regard to the application of the test were observed in the case of cows offered for sale at auction as having passed a tuberculin test.

Pasteurisation.

It is too early for useful comment on what has been done under the Order in connexion with the use of the special process of pasteurisation for milk there defined. Manufacturers of dairy appliances have manifested considerable activity and ingenuity in devising apparatus which would enable the process to be carried out strictly in accordance with the requirements of the Order. Dr. Hamill's "Notes"[2] give a brief account of the nature and object of pasteurisation and the part which it may legitimately play in securing a safe and satisfactory milk-supply. They are also intended to serve as a guide to local authorities and others in respect of essential requirements in the design and construction of pasteurising appliances, which should be complied with in order to satisfy the provisions of the Order in regard to pasteurised milk.

The Handling of Milk.

Inquiries into the conditions under which milk is handled during transport are being carried out by the Ministry, and observations in regard to this matter are being made at the present time at the principal London railway stations. Special attention is also being given to bottling of milk. The very general practice of delivering milk from door to door in small cans filled as required from churns carried on a cart or barrow has objections owing to the contamination which the milk may receive from splashings, dust, and other inevitable pollutions from the street, and from the hands of the roundsman, who, besides handling the milk, has to drive a horse or push a barrow. The obvious nature of these objections has for long been recognised, and the delivery of milk in suitable bottles (sterilised by steam, filled under hygienic conditions in a properly conducted dairy and securely sealed) will afford adequate protection against any further contamination of the milk, not only in course of delivery, but also in the household up to the moment of its actual consumption.

The public have begun to realise the advantages which bottled milk should possess, and the demand for it is increasing. This demand is unfortunately being widely exploited by the less scrupulous section of the milk trade. Instead of the milk being bottled under strictly hygienic conditions at a proper dairy it is very frequently bottled by the roundsman in the street. A bottle which has been carried on the cart exposed to the dust of the street, or perhaps collected as an "empty" from a neighbouring customer, is filled at the tap of the churn, fitted with a cardboard disc taken by the roundsman from his pocket, or where several bottles have to be covered at the same time, from a store of discs held between his teeth, and presented to the unsuspecting customer as "Nursery Milk" or milk of some other fanciful designation of the kind. For this the consumer confidingly pays an extra price, although milk so handled is in reality much less safe than milk delivered in ordinary cans. Powers for prohibiting practices of this kind will be available when the Milk and Dairies (Consolidation) Act comes into operation in the autumn of 1925. In the meantime consumers should satisfy themselves beforehand that bottled milk has really been bottled in a proper manner.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Medical and Pharmaceutical Advertisements.

A MOTION was laid before the Chamber of Deputies with regard to the prohibition of publicly advertising medical treatment or pharmaceutical preparations. This motion is designed to protect the public health which is threatened by the advertisements of those who claim to cure rheumatism, hernias, tuberculosis, and syphilis, and to combat the publication of announcements so worded as to induce readers to believe that they can dispense with proper medical care. The motion is particularly directed against proprietary medicines the ingredients of which the makers will not disclose in spite of the law against secret remedies, and aims at suppressing medicines accompanied by instructions for self-treatment by the purchaser, which involves transgress of the law dealing with illegal medical and pharmaceutical practice. The motion contains a unique clause which runs as follows: "From the date that this law comes into force, all publicity carried out by means of the press, by posters or otherwise, to further the medical or pharmaceutical treatment (excepting such advertisements in scientific journals published on behalf of the medical profession) will be punishable by imprisonment from five days to a month, and by a fine of 500 to 3000 francs, or by one of these penalties alone. Where the offence is repeated the punishment will be doubled."

A Proposed Sanatorium for Tuberculous Students.

The Section of Medicine of the Association Générale des Étudiants has given consideration to the question of tuberculous students in France, and now proposes to establish a sanatorium on the lines adopted by certain other industrial and university societies for their members, as, for example, the Metallurgic and Miners' Society. The site of the proposed sanatorium lies on the plateau of Petites Roches, at an altitude of 1100 metres, some 18 kilometres from Grenoble. The plans provide for a basement, a ground floor, and three upper storeys. The third storey will be erected only over the central portion of the building, and the kitchen will be situated apart from the house. In layout the sanatorium will be fan-shaped, two wings forming an open angle with the central portion, which will face south, an open gallery on the southern side will run the whole length of the ground-floor. There will be accommodation for 103 beds divided among 32 rooms each containing two beds, the other rooms being used for isolation cases. A certain number of beds will be reserved for cases of bone tuberculosis and for women students. A games room, a library, and experimental laboratories are included in the plans. The State has granted to the Association the sum of 1,300,000 francs towards the cost of establishing the sanatorium, the total expenses of which are estimated to be double that amount.

Infant Welfare Propaganda.

The Prefect of the Seine recently brought before the Academy of Medicine a proposal to publish a brochure on infant welfare, for distribution amongst the mothers of the community. The Academy, however, was of the opinion that such a pamphlet would have no greater efficacy than the health instruction posters already exhibited in many places, and that to further the cause of infant welfare the best method would be to increase the number of such posters, rather than to publish more detailed instructions in the form of a brochure.

A New Doctorate.

The diploma of "Veterinary Doctor" was established by law a year ago and the conditions under which this title of doctor may be granted to those who hold the ordinary veterinary diploma have recently been determined. The students of the National Veterinary Schools of Alfort (near Lyons), Paris, and Toulouse must submit a printed thesis to the Faculty of Medicine at their respective schools. The examining body will consist of three members, a professor of the Faculty of Medicine as president and two professors from the veterinary school. In future every veterinary student must qualify with the Diploma of Veterinary Doctor. Veterinary practitioners, under the old scheme, may obtain the new title by submitting a thesis, or in lieu, by showing a satisfactory record of previous work. Professors and former professors of the National Veterinary Schools will receive the diploma of doctor without submitting a thesis.

The "Journées Médicales" at Toulouse.

The success which has attended the Journées médicales of Brussels, which have been held annually during the last four years, incited the medical men of Toulouse to hold a similar type of local conference. These journées médicales differ from the usual congress or conference in that they are designed purely for local practitioners who cannot spare much time away from their practices, with the object of passing under review most of the problems which are of topical scientific and professional interest. Last month, therefore, Dr. Bardier, professor of experimental medicine at the University of Toulouse, assisted by the Dean, Dr. Abelous, organised with great success journées held on four days and attended by some 650 medical men. Every morning the members were given a detailed programme of the various clinical meetings, medical and surgical, that were being held in the various hospitals. In the afternoons conferences were held at the Faculty of Medicine. Among the communications made I might mention those of Dr. Vincent, Medical Inspector-General, on the colon *bacillus* as a pathogenic agent, on vaccinotherapy, and on the methods employed during the war to combat typhoid fever, gas gangrene, dysentery, and cholera. There was a full exhibition of field laboratory and hospital equipment. Dr. Gley, of the Collège de France, read a paper on the problem of old age and the doctrine of the glands of internal secretion; Dr. Bézy spoke on infant welfare in its sociological aspect; and Dr. Beckers, who represented the Belgian Government, dealt with recent advances in the treatment of cancer of the breast. Medical politics were fully discussed, among the speakers being Dr. Decourt, president of the Union of Medical Syndicates, and Dr. Bellencontre, president of the General Association of French Doctors. Apart from the consideration of scientific and professional questions, a pleasant programme of excursions was carried out and a visit was paid to the thermal establishment at Luchon.

SWITZERLAND.

(FROM OUR OWN CORRESPONDENT.)

Rejection of an Antivivisection Bill.

AFTER the plebiscite in the canton of Basle-Land of August 17th, throwing open medical practice to "homœopaths and herbalists," one had every reason to look forward with grave misgivings to the popular vote in the canton of Zurich of August 31st. A Bill had been brought forward, drafted by a local dentist and supported by some 20,000 citizens, which provided for the complete prohibition of vivisection—operations on animals performed by veterinary surgeons or by farmers for breeding purposes being excepted. Since in the canton of Zurich there existed strict legal provisions regulating vivisection in scientific institutes, it was difficult to see what other object the promoters of the Antivivisection Bill had in view than an attack on medical science generally. In the Cantonal Parliament of Zurich the popular Draft Bill only found one friend who in his speech called the abolition of vivisection "the realisation of a religious and civilising claim," and who could not understand why intelligent animals should have to give their life "in order to cure unreasonable men who had ruined their health by vice and passion." In the campaign preceding the vote organisms per c.cm. If the milk so treated is Grade A milk the number of organisms must not exceed 30,000 per c.cm. and there must be no coliform organisms in 0·1 c.cm. Pasteurisation or heating of Certified or Grade A (Tuberculin Tested) Milk is not allowed.

The number of licensed producers controlled directly by the Ministry at the end of 1923 was 101, an increase of 60 per cent. on the number holding licences at the end of the previous year. During the year 14 new licences for the production of Certified and 24 for Grade A (Tuberculin Tested) were issued, and none was revoked on account of failure to comply with the Order.

Visits by the Ministry's milk inspectors were made to all farms in respect of which licences had been issued directly from the department, and each farm was inspected, on an average, once every six months. Before a new licence is issued the farm of each applicant is inspected and a report made on the special score card which has been adopted by the department. This includes a survey of equipment, methods of production, identification of animals in the herd and checking records of the herd, and of the production and sale of milk.

Records kept in the department indicate that at the end of 1923 approximately 4000 animals were included in those licensed herds for which a tuberculin test is prescribed by the Order (2200 on "Certified" farms and 1800 on "Grade A (Tuberculin Tested)" farms). The milk of these grades produced during the year amounted approximately to 6000 gallons daily.

Bacteriological Examination.

Samples of milk taken for this purpose are now in all cases obtained by officers of the various local authorities in whose districts the milk is sold and are despatched by them to the bacteriological laboratory with which the local authority, with the approval of the Ministry, has arranged for the examination of these samples. The reports indicate in general a very high standard of achievement on the part of the producers concerned. In 1923, 83·4 per cent. of the samples examined were within the limits prescribed by the Order, compared with 76 per cent. in 1922, 71·8 per cent. in 1921, and 69·7 per cent. in 1920. Copies of the bacteriologist's report are in all cases sent to the producer, his attention being drawn, where necessary, to any departure from the prescribed limits. Where such has occurred a second sample is taken shortly afterwards, and if necessary a third. It is seldom, however, that the cause of failure has not been removed by the time a second sample is taken. The disclosure which the bacteriological method of control inevitably makes of failure to observe any of the essential details of clean milk production, as well as the general accuracy and fairness of the method are understood and appreciated by producers and others engaged in the trade.

Under the new Order the conditions required in connexion with the tuberculin testing of licensed herds have been revised in some particulars. These include re-tests at six-monthly intervals by the combined subcutaneous and ophthalmic methods and involve the taking of two additional pre-inoculation temperatures and one additional post-inoculation temperature at the sixth hour. These modifications were made on the recommendation of the Tuberculin Committee of the Medical Research Council, whose earlier work in the investigation of this test as applied to cattle strongly indicated the desirability of adopting these modifications. The work of this Committee has continued throughout the year, and the department is indebted to its members and especially to its chairman, Captain S. R. Douglas, for much very helpful coöperation in dealing with the many problems which have arisen in connexion with the application of the tests. It is hoped that the ultimate outcome of the Tuberculin Committee's work will be to simplify and standardise these tests and at the same time enhance their reliability and value as a diagnostic method.

The sale of stock advertised as having passed the tuberculin test appears to be on the increase. The tests in question have not always been carried out in accordance with the requirements of the Order, and licensed producers buying such animals at auction sales have been faced with the difficulty that the certificates are not accepted by the Ministry. Before adding such animals to the licensed herds licensees have been obliged to submit them to a special test which has been devised to meet such cases, but this involves additional expense, trouble, and loss of time to the producer, and it would obviously be desirable in the interests of all concerned if the Ministry's requirements in regard to the application of the test were observed in the case of cows offered for sale at auction as having passed a tuberculin test.

Pasteurisation.

It is too early for useful comment on what has been done under the Order in connexion with the use of the special process of pasteurisation for milk there defined. Manufacturers of dairy appliances have manifested considerable activity and ingenuity in devising apparatus which would enable the process to be carried out strictly in accordance with the requirements of the Order. Dr. Hamill's "Notes"[2] give a brief account of the nature and object of pasteurisation and the part which it may legitimately play in securing a safe and satisfactory milk-supply. They are also intended to serve as a guide to local authorities and others in respect of essential requirements in the design and construction of pasteurising appliances, which should be complied with in order to satisfy the provisions of the Order in regard to pasteurised milk.

The Handling of Milk.

Inquiries into the conditions under which milk is handled during transport are being carried out by the Ministry, and observations in regard to this matter are being made at the present time at the principal London railway stations. Special attention is also being given to bottling of milk. The very general practice of delivering milk from door to door in small cans filled as required from churns carried on a cart or barrow has objections owing to the contamination which the milk may receive from splashings, dust, and other inevitable pollutions from the street, and from the hands of the roundsman, who, besides handling the milk, has to drive a horse or push a barrow. The obvious nature of these objections has for long been recognised, and the delivery of milk in suitable bottles (sterilised by steam, filled under hygienic conditions in a properly conducted dairy and securely sealed) will afford adequate protection against any further contamination of the milk, not only in course of delivery, but also in the household up to the moment of its actual consumption.

The public have begun to realise the advantages which bottled milk should possess, and the demand for it is increasing. This demand is unfortunately being widely exploited by the less scrupulous section of the milk trade. Instead of the milk being bottled under strictly hygienic conditions at a proper dairy it is very frequently bottled by the roundsman in the street. A bottle which has been carried on the cart exposed to the dust of the street, or perhaps collected as an "empty" from a neighbouring customer, is filled at the tap of the churn, fitted with a cardboard disc taken by the roundsman from his pocket, or where several bottles have to be covered at the same time, from a store of discs held between his teeth, and presented to the unsuspecting customer as "Nursery Milk" or milk of some other fanciful designation of the kind. For this the consumer confidingly pays an extra price, although milk so handled is in reality much less safe than milk delivered in ordinary cans. Powers for prohibiting practices of this kind will be available when the Milk and Dairies (Consolidation) Act comes into operation in the autumn of 1925. In the meantime consumers should satisfy themselves beforehand that bottled milk has really been bottled in a proper manner.

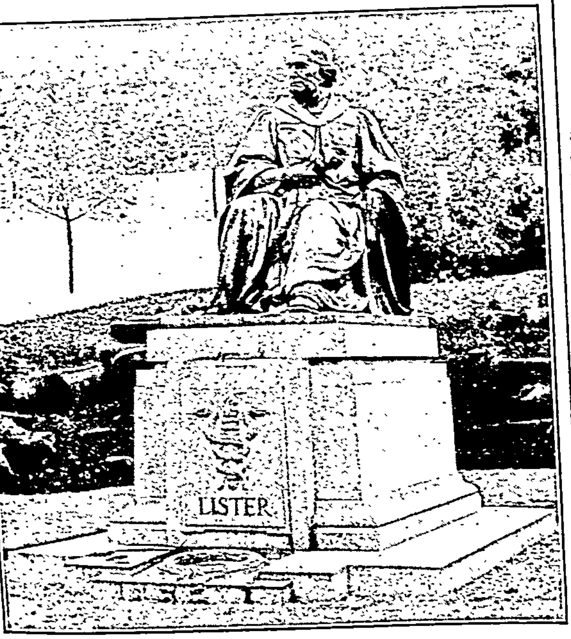
[2] Reports on Public Health and Medical Subjects, No. 17. Notes on the Pasteurisation of Milk, by Dr. J. M. Hamill.

GLASGOW MEMORIAL TO LORD LISTER.

THE movement to commemorate the great services of Lord Lister in the city in which he made, and put into practice, the discoveries which have done so much for the alleviation of human suffering, originated as far back as February, 1912, when a committee of citizens was appointed to promote the memorial and obtain the subscriptions therefor, but owing to the war the prosecution of the scheme was interrupted. The appeal for funds was most generously responded to, and the scheme generally met with the most unqualified approval. Subscriptions were received from individuals and scientific societies in this country and abroad. Various suggestions were made as to the most fitting manner in which Lord Lister's memory should be commemorated. One of the proposals which received almost universal support was the preservation of the old "Lister Ward" in the Glasgow Royal Infirmary, with the idea of making the ward a medical museum not only for the housing of personal relics of Lord Lister and of his period, but also to demonstrate the evolution of the science and art of surgery since his day. However, the managers of the Royal Infirmary declined to entertain the proposal and caused the historic ward to be demolished, notwithstanding widespread protest not only from the citizens of Glasgow but from scientific men and scientific bodies all over the world. In the course of their labours the committee collected—largely through the personal efforts and enthusiasm of Mr. A. E. Maylard, who until recently was the senior surgeon of the Glasgow Victoria Infirmary—a number of valuable objects of interest and other relics relating to the life and period of Lord Lister, including several portraits of him; photographs of the houses and institutions with which he was connected; several documents and autograph papers; his robe, hoods, and trencher; a hundred of his books; models of old operating tables and various instruments; specimens of the dressings used by Lord Lister; examples of sprays and other apparatus which belonged to Lord Lister, and various pieces of old furniture. This collection is at present being temporarily housed in the Pathological Department of the Royal Infirmary.

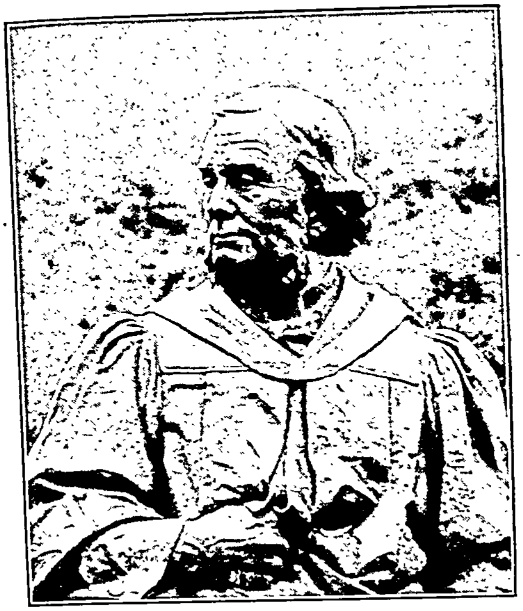
FIG. 1.



STATUE IN KELVINGROVE PARK.

When the Memorial Committee realised that the decision of the directors of the Royal Infirmary to demolish the ward was irrevocable it was decided to apply the funds at the committee's disposal to the erection of a statue of Lord Lister to be placed in the Kelvingrove Park, immediately below the University of Glasgow, of which he was at one time so distingusihed an ornament, and on a site adjacent to the one occupied by a similar statue of his old contemporary and colleague, Lord Kelvin. This statue, designed by Mr. Paulin, A.R.S.A., which shows Lister in his robes, seated, was unveiled on Sept. 17th by Sir Hector C. Cameron, emeritus professor of surgery in the University of Glasgow, and one of the last survivors of Lord Lister's house-surgeons and assistants. No more appropriate choice could have been made than of one who throughout his life retained the affection and regard of his great master.

FIG. 2.



LORD LISTER.

In the course of his speech Sir Hector Cameron gave an interesting account of the surgery class in the University of Glasgow in 1862, when Lister was professor. "One of my fellow students," he said, "was Frederick Trendelenburg. Some years ago, in a letter which I received from him, he observed that, while we all regarded Prof. Lister with great respect and admiration, none of us could foresee that he would one day 'change surgery from the very bottom.' This was a just remark. All of us, indeed, felt conscious that we were listening to new and valuable lessons not yet in print, but little realised how great their value was or what unspeakable blessings were to flow from their development in the near future. It was not, however, until 1865 that Lister began to develop his antiseptic system of wound treatment. His subsequent achievements were not accomplished without indomitable perseverance and a marvellous patience in the face of great opposition from the majority of the leaders of his profession, especially in his own country. From the very first he was under no illusion in regard to the inevitable and hostile criticism which his doctrines must evoke, especially from those who were prejudiced by a life-long familiarity with the older teaching and the former methods of practice. Years later Lister said on one occasion that no demagogic device was spared to attack the legitimate methods of medical science; the anti-vivisection propagandists widely used sensational illustrations. The electorate of Zurich kept a cool head and rejected the Bill with 62,641 votes against 27,793.

The Epidemic of Mild Small-pox.

The epidemic of small-pox in Switzerland which began early in 1921 has not yet subsided. According to the annual report of the Federal Health Office in 1923, 2145 cases were notified in 1923 and 1159 cases in 1922. Small-pox here has maintained the same mildness of type as observed in the epidemic in England; so far only one death, that of an enfeebled man of 69, has been reported. Investigation into the state of vaccination amongst the small-pox patients has shown that of the 2145 cases in 1923 1791 had never been vaccinated. The epidemic is practically confined to the German-speaking cantons. This is easily explained by the fact that in the French and Italian-speaking cantons vaccination is compulsory, and the law is strictly enforced. The present epidemic puts a heavy financial burden on the country; in the last two years over a million francs (£40,000) have been spent in isolation of cases, disinfection, and transport.

Medical Study.

The number of candidates for the federal medical examinations begins to show a slight decline. In 1923 223 candidates presented themselves for the first and second examinations and 180 for the final examinations, the corresponding numbers for 1922 having been 243 and 196. This decline is welcome, although the danger of overcrowding of the profession still exists, as an annual increment of 180 qualified practitioners is far above the demand in our small country. A post-graduate course for public health officers and police surgeons, arranged by the medical faculty, will be held at Basle from Oct. 1st to 21st. Amongst the subjects which are treated by prominent Swiss scientists may be mentioned sickness and accident insurance, school and industrial hygiene, organisation of first-aid stations, regulation of midwives, food control, anthropometry, forensic medicine, modern methods of combating epidemics, and venereal disease. Apart from the lectures the sanitary institutions of the town and some industrial works will be visited. The course is open to all medical men. No fee is charged. Intending participators should apply to Prof. Doerr, Institute of Hygiene, Basle.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Death of Prof. August Reuss.

A FEW days ago the senior of our ophthalmic surgeons, Prof. Dr. August Reuss, passed away at the age of 83 years. He was a descendant of a well-known medical family, and his son is professor of pediatrics in Vienna University. As a young man Prof. Reuss took up the study of botany, but he soon turned his attention to medicine, and became assistant of Arlt. He worked chiefly on the purely optic side of ophthalmology, and contributed valuable papers and books on colour-blindness, on the visual field in functional diseases of the nervous system, and on the hygiene of schools from the standpoint of the eye specialist. For a short time he was director of the Eye Clinic in Vienna, when Stellwag and Mauthner passed away in rapid succession. Then he founded the "Poliklinik," an institute that, under his energetic management, succeeded in becoming a second "general hospital" and almost a second University, for all the subjects of the medical student's curriculum—except anatomy—were taught at the "Poliklinik" by most competent men. In fact, an appointment to a professorship at this institute was, and is still, regarded as the last step before being called to a chair at the Vienna University. The deceased was the recipient of numerous honours during his long life, and honorary member of nearly all the ophthalmic societies of Europe.

Privileges for Doctors' Cars in Street Traffic.

In a memorandum to the Ministry of Commerce (which controls the traffic and transport here) the Medical Union demands that cars owned or run by doctors in the course of their medical work should be allowed to exceed the speed limit with impunity. This privilege is accorded only to the public first-aid ambulance and the fire-brigade, and at present the police controlling the street traffic give a certain preference to motor-cars showing the word "Arzt" (medical man) across the front. But the medical men demand to be treated on the same lines as the other two above-mentioned groups, because the urgent calls of a doctor are of equal importance. It is believed that within a short time the preferential treatment of most professional calls will be conceded by the police.

Athletes' Hearts.

The institute known as "Herzstation" (department for study of the diseases of the heart) has organised a regular examination of the hearts of individuals devoting themselves to gymnastic or athletic sports. For the last two years all the prominent members of our leading football, swimming, and boxing clubs have been examined at regular intervals, also before and after special feats, and exact records taken, including X ray photos, electro-cardiograms, and the results of functional tests. Besides, about 4500 individuals of both sexes, of ages between 14 and 36, engaged in more or less active muscular exercise, have been examined in this institute and the observations obtained thus are kept for comparison at later periods, when these individuals come back for re-examination. Valuable knowledge was obtained in this way and formed the basis of a book published by Dr. Kauf, dealing with the sporting man's heart. It is now intended to send for examination all children of 14 or over who frequent the higher schools before permitting them to take up athletics.

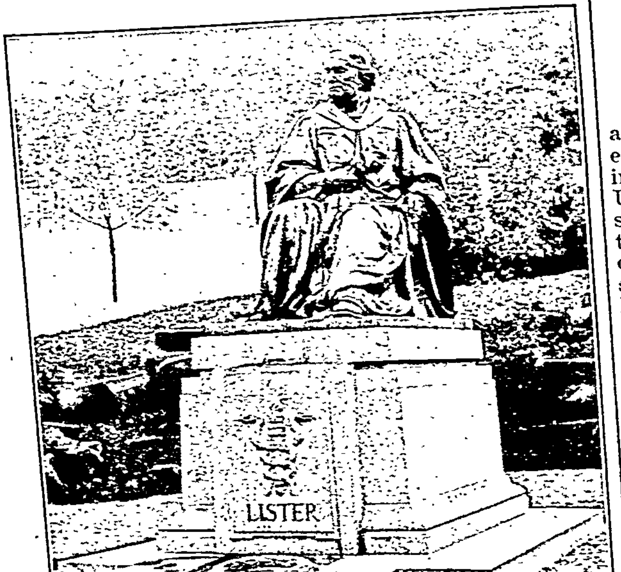
BELFAST MENTAL HOSPITAL.

THE annual report of the Belfast Mental Hospital for the year 1923 shows that the number of patients under treatment during the year was 997—males 480, females 517. The most prevalent form of mental disorder was melancholia —22·5 per cent. (15 males and 37 females), followed next by primary dementia, 16·4 per cent. (29 males and 9 females). General paralysis was represented by 28 males and 7 females, an increase of 20 over the previous year. Eight males and five females were cases of congenital mental deficiency. One hundred and forty-two patients were discharged; of these 88 were recovered, the recovery-rate to the total number of admissions being 38·1 per cent. This rate remains about the same as in previous years. The deaths were 71 (33 males and 38 females). The chief causes of death were general paralysis, which accounted for 22·5 per cent., cerebral softening with 16·9 per cent., and phthisis with 15·4 per cent. The chief causes of mental disorder were found to be morbid heredity, mental stress, the critical periods, and syphilis. In 4·3 per cent. of the admissions alcoholic excess was considered the principal cause of insanity, and in 9·5 per cent. it was believed to be a contributory cause. The treatment of general paralysis of the insane by the induction of malarial fever was commenced late in the year. Benefit has accrued in certain cases, but the medical superintendent, Dr. S. J. Graham, thinks it premature to decide whether the improvement will be permanent. Dr. Graham urges the necessity for fresh lunacy legislation in order to deal effectively with prevention and the incipient stages of mental disease. He urges that "it seems pitiable that one of the worst forms of disease should be denied skilled early treatment, and that it is not until the mental symptoms have developed so far as to render the individual unfit to be at large does treatment commence, following certification and its present-day attendant stigma." This matter has already been brought officially under the notice of the Government of Northern Ireland, and it is hoped that the necessary legislation will not be long delayed. The committee of the hospital has already arranged for the erection of a reception villa for incipient cases, which may hereafter be admitted as voluntary or uncertified patients.

GLASGOW MEMORIAL TO LORD LISTER.

THE movement to commemorate the great services of Lord Lister in the city in which he made, and put into practice, the discoveries which have done so much for the alleviation of human suffering, originated as far back as February, 1912, when a committee of citizens was appointed to promote the memorial and obtain the subscriptions therefor, but owing to the war the prosecution of the scheme was interrupted. The appeal for funds was most generously responded to, and the scheme generally met with the most unqualified approval. Subscriptions were received from individuals and scientific societies in this country and abroad. Various suggestions were made as to the most fitting manner in which Lord Lister's memory should be commemorated. One of the proposals which received almost universal support was the preservation of the old "Lister Ward" in the Glasgow Royal Infirmary, with the idea of making the ward a medical museum not only for the housing of personal relics of Lord Lister and of his period, but also to demonstrate the evolution of the science and art of surgery since his day. However, the managers of the Royal Infirmary declined to entertain the proposal and caused the historic ward to be demolished, notwithstanding widespread protest not only from the citizens of Glasgow but from scientific men and scientific bodies all over the world. In the course of their labours the committee collected—largely through the personal efforts and enthusiasm of Mr. A. E. Maylard, who until recently was the senior surgeon of the Glasgow Victoria Infirmary—a number of valuable objects of interest and other relics relating to the life and period of Lord Lister, including several portraits of him; photographs of the houses and institutions with which he was connected; several documents and autograph papers; his robe, hoods, and trencher; a hundred of his books; models of old operating tables and various instruments; specimens of the dressings used by Lord Lister; examples of sprays and other apparatus which belonged to Lord Lister, and various pieces of old furniture. This collection is at present being temporarily housed in the Pathological Department of the Royal Infirmary.

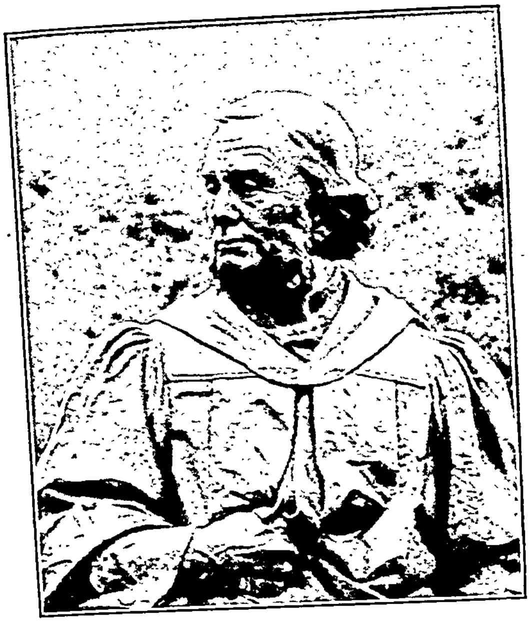
FIG. 1.



STATUE IN KELVINGROVE PARK.

When the Memorial Committee realised that the decision of the directors of the Royal Infirmary to demolish the ward was irrevocable it was decided to apply the funds at the committee's disposal to the erection of a statue of Lord Lister to be placed in the Kelvingrove Park, immediately below the University of Glasgow, of which he was at one time so distingusihed an ornament, and on a site adjacent to the one occupied by a similar statue of his old contemporary and colleague, Lord Kelvin. This statue, designed by Mr. Paulin, A.R.S.A., which shows Lister in his robes, seated, was unveiled on Sept. 17th by Sir Hector C. Cameron, emeritus professor of surgery in the University of Glasgow, and one of the last survivors of Lord Lister's house-surgeons and assistants. No more appropriate choice could have been made than of one who throughout his life retained the affection and regard of his great master.

FIG. 2.



LORD LISTER.

In the course of his speech Sir Hector Cameron gave an interesting account of the surgery class in the University of Glasgow in 1862, when Lister was professor. "One of my fellow students," he said, "was Frederick Trendelenburg. Some years ago, in a letter which I received from him, he observed that, while we all regarded Prof. Lister with great respect and admiration, none of us could foresee that he would one day 'change surgery from the very bottom.' This was a just remark. All of us, indeed, felt conscious that we were listening to new and valuable lessons not yet in print, but little realised how great their value was or what unspeakable blessings were to flow from their development in the near future. It was not, however, until 1865 that Lister began to develop his antiseptic system of wound treatment. His subsequent achievements were not accomplished without indomitable perseverance and a marvellous patience in the face of great opposition from the majority of the leaders of his profession, especially in his own country. From the very first he was under no illusion in regard to the inevitable and hostile criticism which his doctrines must evoke, especially from those who were prejudiced by a life-long familiarity with the older teaching and the former methods of practice. Years later Lister said on one occasion that 'he had often thought that if he did deserve any credit at all it was at the time when, perfectly convinced of the truth of the principle on which he acted, and persuaded also of the enormous importance to mankind of being able to carry out that principle in practice, he worked for years together with exceedingly little encouragement from his professional brethren. There were two great exceptions, however, his father-in-law (Prof. Syme, of Edinburgh) and his students.' "

The Lord Provost of Glasgow, who is chairman of the Lord Lister Memorial Committee, presided at the ceremony, and amongst those present were the Lord Provost of Edinburgh, Sir Donald MacAlister, Principal of Glasgow University, Sir William Watson Cheyne, ex-President of the Royal College of Surgeons of England, Sir Harold J. Stiles, President of the Royal College of Surgeons, Edinburgh, Prof. T. K. Monro, President of the Royal Faculty of Physicians and Surgeons, Glasgow, Sir Thomas Oliver, of Newcastle-on-Tyne, Lord Blythswood, and Lord Maclay.

Medicine and the Law.

INQUEST VERDICT AGAINST A MEDICAL MAN.

AN inquest was held recently at Gloucester upon the body of Nellie Burnham, 10½ years of age, the daughter of a steel presser, working in America, who died on August 10th. At the conclusion of the evidence the jury returned a written verdict that "the child died from diphtheria and pneumonia, and that Dr. Hadwen failed to show competent skill and special attention, in consequence of which failure the child died." The coroner (Mr. G. Trevor Wellington) said that this in law was a verdict of manslaughter and committed upon his warrant Dr. W. R. Hadwen to take his trial at the next Gloucester assizes, allowing bail. Since then Dr. Hadwen has been brought before the magistrates and remanded on bail upon the same charge, only formal evidence being given.

At the inquest the evidence of the mother was to the effect that she called in Dr. Hadwen on August 1st to see the deceased child, who had a bad throat and talked thickly. Dr. Hadwen ordered a gargle of warm water and vinegar. He examined the child's throat, chest, and back. He saw the child again on the 4th and 6th, and told her to paint her throat with glycerine as she could not gargle. On the 9th Dr. Hadwen saw the child at 10.30 A.M., made an examination, and, according to the witness, said that there was scarcely anything the matter, and that the child would soon be well. She also said that he was in the house for only five minutes. He told her to give the child, who could not keep down the milk which he had ordered previously, milk diluted with water. A consultation of relatives was held during that day, as the result of which Dr. E. S. Ellis was called in and saw the child at 10.15 P.M. He diagnosed diphtheria and pneumonia, and held out little hope of the patient living. She died soon after midnight (12.50 A.M., August 10th). The witness said she had suspected diphtheria, but had not said so to Dr. Hadwen. Dr. Hadwen had attended other children of hers, who since he did so had been removed to the isolation hospital. Recalled later, she admitted in cross-examination that the child two days before her death had got out of bed and gone down barefoot to the kitchen to get a drink of water, and that she had not told Dr. Hadwen of this.

Dr. Ellis gave particulars of his examination of the deceased whom he found suffering from diphtheria, bronchitis, and pneumonia. He had little expectation that the child would recover, and notified the case as diphtheria. If he had found the earlier symptoms described by the mother he would have taken a swab, also pulse and temperature. He criticised the treatment ordered by Dr. Hadwen as of little value, and thought that proper treatment and accurate diagnosis ought to have saved the patient's life. He had not given a certificate as he had not attended during the illness.

An aunt of the mother corroborated her evidence as to Dr. Hadwen having said there was little the matter with the child on the morning of the 9th.

Dr. R. B. Berry, city medical officer of health, said he had received no notification of diphtheria affecting the Burnham's house from Dr. Hadwen.

Dr. W. Washbourn gave details of the condition shown by post-mortem examination. Death, in his opinion, was due to diphtheria and pneumonia. Leaving bacteriology out of the question, he thought a medical man should at least have suspected diphtheria from the clinical symptoms. Dr. Washbourn, cross-examined on behalf of Dr. Hadwen as to the incident of the child getting water from the kitchen, said that it might have resulted in a chill and brought on pneumonia. From the condition of the bronchial tubes and the adherent membrane he would ascribe death to diphtheria rather than to pneumonia.

A neighbour, whom the mother had told about the child fetching water, and who had communicated with Dr. Hadwen's solicitor, also gave evidence.

Dr. Hadwen, who was called and cautioned, declared himself willing to give evidence, and contradicted the statements of the mother in several particulars, stating that his visits had been longer and his examinations more detailed than she had described. He had attended a brother and sister of the deceased in July, and had found in them no symptoms of diphtheria, after considering the question whether they were suffering from it. On August 1st he had found the deceased suffering from a bad cold, had considered the question of diphtheria, and came to the conclusion that her case was similar to that of her brother and sister. He described her symptoms and his treatment in detail, stating that he had found the latter effective in similar cases. He had felt the child's pulse, usually looking at the throat at the same time, on each occasion that he had been to the house. He maintained that it was easy to diagnose diphtheria, as the membrane could not be mistaken. He did not take a swab because the diphtheric bacillus was found in every kind of sore-throat and in the majority of healthy throats. Several questions were asked as to this by the coroner, Dr. Hadwen maintaining his opinion and saying finally, "I should like to point out that the modern germ theory is all bosh." He said that there was no clinical symptom or physical sign of diphtheria in the deceased from first to last, but that when he saw her on the 9th there was a marked change in her condition and "inflammation of the right lung, known as croupous pneumonia." He had tried to find out the cause of the change, but had not been told of the child going downstairs. He had not told the mother that there was little the matter. Such a suggestion was absurd. He had advised her to give milk, and said it was the child's only chance, but had avoided frightening the mother as well as he could. He was emphatically of opinion that the child contracted pneumonia in going downstairs and died from pneumonia. The witness expressed at length his views on the bearing of the conditions observed by him and those revealed by the post-mortem examination upon this point.

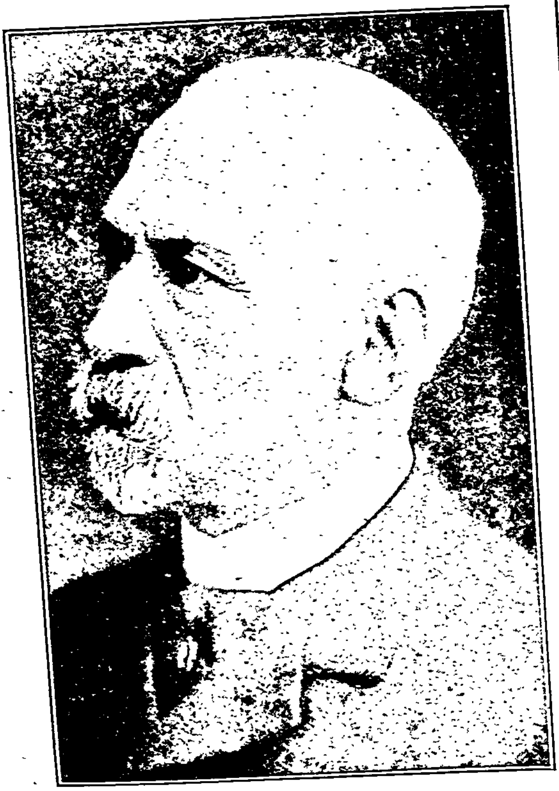
The coroner, in addressing the jury, explained the distinction between negligence and gross negligence as affecting their verdict, and drew their attention to the contradictions in the evidence. They had to determine (1) whether diphtheria was the cause of death; (2) whether there was negligence by reason of failure to use competent skill and/or to give sufficient attention; (3) if they thought there was negligence, did they think it was gross? Finally, did they believe that the negligence caused contributed to or accelerated the death of the deceased? The jury's answer, which it will be observed does not follow strictly the lines suggested by the coroner, is given above.

Obituary.

SIR FREDERICK NEEDHAM, M.D. St. And.,

COMMISSIONER OF THE BOARD OF CONTROL.

The death of Sir Frederick Needham, for 27 years Commissioner of the Board of Control, which took place at the advanced age of 88 on Sept. 6th at his residence in Bournemouth, severs an important link with the past in the study and treatment of mental disorders, and with the numerous improvements that have taken place during the past three-quarters of a century in the conditions under which insane patients are housed and treated.



Sir Frederick Needham.

The second son of Dr. James Peacock Needham, he was born at York, where he received his early education at St. Peter's School. He studied medicine at St. Bartholomew's Hospital, London, and qualified M.R.C.S. in 1858, and M.D. St. And. in 1862. Three years later he became a Member of the Royal College of Physicians of Edinburgh. On qualifying at the age of 22, Needham was appointed to the medical superintendentship of the York Hospital for the Insane (Bootham Park). Those were the days when an active campaign was still being conducted by the most enlightened of the physicians in mental disorders against the systematic use of mechanical restraint and other allied forms of treatment which, happily in this country, have long ago been discarded. Of all these devices Needham was always a stern opponent; even as respects forced alimentation by the nasal or œsophageal tube, salutary and life-saving as he admitted them to be when promptly and judiciously used, he urged that there were not a few cases in which rectal feeding was kinder, safer, and as efficacious. In this connexion and to anticipate for a moment his work as a Commissioner, it is of interest to know that it was he who, on behalf of the Board, drew up not only the Regulations made under the section in the Lunacy Act dealing with mechanical restraint, but also the definition of "seclusion"—the steady enforcement of both of which has left so deep a mark in the better treatment of the insane. Much good work was done by Needham at Bootham Park, and when he left in August of 1874 to take up the post of superintendent at Barnwood House (Gloucester)—another well-known hospital for the insane—it was in no uncertain terms that the committee of governors testified to the energy, zeal, ability, and success with which he had discharged very onerous duties during a period of 16 years.

By a somewhat curious coincidence, it was for a nearly identical period—a few months more—that he was destined to preside at Barnwood. This hospital already enjoyed a high reputation; but Needham with his now matured experience and foresight, and with the support and goodwill of his committee, was able to effect various developments and adaptations—all of which materially added to the comfort of the patients and the efficiency of their treatment and have stood the test of time—and he left the hospital occupying a still more honourable and important position. While at York he had married Charlotte, the daughter of the Rev. J. Shooter, vicar of Bishop Wilton in Yorkshire, whose wisdom and the influence of whose personality were of signal help to her husband in his work at Barnwood; and, when they left, a graceful tribute to her voluntary assistance was paid by the governors of the hospital. She died in 1907, and a stained window to her memory was placed in the chapel of the hospital.

It was in April, 1892, when Sir Clifford Allbutt relinquished his Commissionership upon being called to Cambridge as Regius Professor of Physic, that Dr. Needham was offered and accepted the post of Commissioner in Lunacy, a position he filled with conspicuous distinction until his retirement in June, 1919, and it was naturally in this capacity that his influence came to be most widely felt. Tall, dignified in appearance, and fearlessly outspoken he was by some held somewhat in awe, especially in his early days as a Commissioner; but whatever austerity of manner there may have been—and he could, indeed, be stern when occasion demanded it—this was very superficial, and closely beneath it was a kindliness of heart, a uniformly good temper, and a full measure of that spirit of helpfulness which has been said to give to the profession of medicine its value to humanity. Broad-minded, peculiarly tolerant of opposition and of the views of others, a most patient listener to conflicting claims, and endowed with a keen sense of justice, his judgment, opinion, and advice were of immense value and weight to the Board of Control; and it was no wonder that, when he decided to retire, his colleagues, by each and all of whom he was revered, felt his loss to be irreparable. He had a vitality, mental and physical, which enabled him, right up to his retirement and despite his advanced age, to do his full share of travelling and official visits.

If some characteristic of his attitude towards his position be sought, it can safely be said that, over and above the inspectorial and advisory duties of the Board, he always considered that any question affecting personal liberty and the propriety of remaining under certificates was of paramount concern, and that it was of vital importance to maintain a close and individual touch between the Commissioners and the patients to whom the former should at all times, either at visits or through the post, extend a sympathetic ear. His so often reiterated question, "How will this affect the patients?" might, indeed, be quoted as his work's motto. That a large section of the patients were conscious of the friend they had in Sir Frederick Needham is testified by their numerous inquiries addressed to his former colleagues as to his welfare.

In disposition somewhat retiring, Sir Frederick Needham was no recluse. In 1904 a Royal Commission on the Care and Control of the Feeble-Minded was set up, of which he was an active member. This

Commission undertook a very extensive survey of the problem, visiting various districts of England, Scotland, and Ireland, as also America and several countries of Europe. He also held office in many societies. He was at one time president and subsequently honorary member of the York Medical Society and of the Gloucestershire Medical and Surgical Association; in 1887 he was president of the Psychological Association of Great Britain and Ireland; in 1890 he was president of the Psychological Section of the British Medical Association, and he enjoyed honorary membership in the Medico-Legal Society of New York. He was a member of the Council of Epsom College. He contributed a number of thoughtful and valuable papers to medical literature; in which connexion, as characteristic of his loyalty, mention may be made that, while in his 1890 presidential address he strenuously deprecated, among other matters, the function of the magistrate in the making of reception orders as being likely to delay and hamper treatment in early stages of mental illness, he was as a Commissioner inflexible in seeing that the provisions of the Lunacy Acts and, later, of the Mental Deficiency Act were duly carried out. In 1871 he published a paper on the necessity for legislation in reference to habitual drunkards, followed a few years later by "Insanity in Relation to Society." Among his works are also "Brain Exhaustion," and "Thirty Years of Lunacy Practice." No servant of the public has better deserved the honour of knighthood, which was conferred upon him in 1915.

In 1913 Sir Frederick Needham remarried, his second wife, by whom he is survived, being Helen, daughter of Mr. W. L. Newman, of York. In the sorrow of her bereavement Lady Needham has the consolation of knowing that, as all her late husband's more intimate friends know, she brought great happiness and comfort to him in his latter years.

C. H. B.

ROBERT JAMES FARMAN, L.M.S.S.A. LOND.

Dr. R. J. Farman, secretary of the London Panel Committee, died last week at the age of 55, after an illness lasting for several months. He was born at Gosport, was educated at Ely School and Charing Cross Hospital, and qualified L.S.A. in 1894. He practised in South Wales until 1910 when he removed to Kennington, where he conducted a large general practice. He was a member of the Local Medical and Panel Committees for the County of London from their formation, retiring from practice upon being appointed secretary to these committees in September, 1920. With a vivid experience himself of general practice in industrial areas, he threw himself wholeheartedly into the interests of insurance practitioners who constantly sought his advice. With a flair for organisation, Dr. Farman was a splendid committee man, one of the rare sort who get things done. Among his activities he was a member of the allocation subcommittee of the London Insurance Committee, a member of the distribution committee, and secretary to the committee of management of the dinner held in connexion with the annual panel conferences.

Dr. B. A. Richmond, an earlier secretary of the London Panel Committee, writes: "Farman will be much missed. He was a loyal colleague and a staunch friend. Brave under great physical disabilities, a man of high ideals, untiring in his efforts for the improvement and efficiency of the insurance service. The practitioners of London are greatly in his debt."

THE LATE DR. ALBERT HAWORTH.

Dr. J. Henry Dible writes: "Haworth's passing will leave a very real gap in the Manchester medical school. His teaching ability was marked and his enthusiasm for chemistry was to him a compelling one and the central note of his character. Touched with something of the artistic temperament, musical, generous in disposition, and with a keen sense of humour, he was an extraordinary likable personality. His popularity was great, both with the students, with whom he never lost touch, and with his friends in the medical school, in whose remembrance he will always live, a bright, human, and lovable figure. His bent was almost wholly chemical, and he was given leave for a period to study the current methods of chemical pathology at St. Thomas's Hospital. On his return to Manchester he organised a department for teaching this subject and was made assistant lecturer in chemical pathology in 1922. In this post he succeeded eminently, having true enthusiasm for his subject and a very genuine gift for teaching it. His keenness and personal method of teaching reacted upon his students, and his course became at once successful and greatly appreciated. At the same time he engaged in research work upon various metabolic problems, especially upon conditions affecting the blood-sugar and, latterly, upon renal function in experimental nephritis."

Correspondence.

"Audi alteram partem."

THE DIAGNOSIS OF A HEALTHY HEART.

To the Editor of THE LANCET.

SIR,—Dr. John Parkinson's address in your issue of Sept. 6th is an excellent and concise summary of the cardiology of the present day, and any physician who knows thoroughly the contents of this article, and can act on them, has little to fear in the way of making grave mistakes. I think perhaps it will be generally agreed that the weakest point with the average general practitioner is his knowledge of heart cases. Many are now able to recognise and treat auricular fibrillation, but it is still quite common to see patients who exhibit merely the phenomenon of premature contractions condemned to a life of invalidism on account of their heart, whereas the heart is perfectly sound. If the general practitioner would realise that so long as a patient exhibits no sign either of shortness of breath or pain in the chest, there is little to worry about as regards stethoscopic findings, fewer people would be condemned to a life of invalidism. Patients so condemned rapidly become cardiac neurasthenics.

There is one statement in the article that I cannot reconcile with the teachings of Sir James Mackenzie and Sir Thomas Lewis. Dr. Parkinson states that paroxysmal tachycardia is "the best example we can quote of a functional heart disease." But is it a functional disease? I have always understood that this condition denotes myocardial changes. Sir Thomas Lewis writes ("Clinical Disorders of the Heart Beat"): "The attacks are themselves important indications of muscle damage, and the attacks frequently place the life of the patient in jeopardy." and again, "The prognosis of the individual attacks contains an element of uncertainty. Death during paroxysms has occurred on not a few occasions." I have never seen a death from paroxysmal tachycardia, but I have seen some cases certainly in a state of jeopardy. Can a "functional" state produce this? If it can, is it functional? We know that in some of these cases the grade of heart failure is sometimes grave in the extreme. We know that œdema of the ankles and face may occur, that blood-stained sputum is brought up, that there may be marked basal œdema (a certain sign of cardiac failure), and that later the patient may collapse and go through the stages of progressive failure, delirium, ascites, general anasarca, and death. We know, too, that cyanosis and general venous engorgement may take place, along with bulging of the liver and even enlargement of the spleen. Can these things be regarded as "functional"? If so, it is a functional disease of the heart that may kill.

With patients with true paroxysmal tachycardia it has been my habit in the past to give the relatives a guarded prognosis: I have stated to them that. although the chances of the condition proving fatal are remote. the patient cannot be regarded as having a sound heart and that catastrophe is possible. Have I been giving a prognosis more guarded than was really necessary? Is one entitled to tell the relatives that the condition is purely functional and that there need be no anxiety?

I am, Sir, yours faithfully,
A. GRAHAM-STEWART.
Margate, Sept. 9th, 1924.

THE PRESENCE OF A THIRD TYPE OF CELL IN THE GLANDS OF THE STOMACH.

To the Editor of THE LANCET.

SIR,—Some recent experiments carried out with certain new staining methods have revealed a third type of cell in the stomach glands. They were first observed in the central portion of the stomach, either wedged in between the oxyntic cells and the peptic cells, or were more frequently situated amongst the peptic cells. They were found scattered singly throughout the glands. The cells are small and granular and have a round nucleus. When stained by a special method their staining is quite different from either the oxyntic or the peptic cells, and, with their special structure and characters revealed, they can be easily seen and differentiated. Their distribution in the stomach of man and various animals is now being investigated, as is also the possibility of there being a similar type of cell in the intestinal glands. It seems possible that the secretion from these cells may play an essential part in activating the pepsinogen.

A full description of these cells and their distribution and the staining methods by which they can be demonstrated will be published.

I am, Sir, yours faithfully,
FREDERICK W. TWORT, M.R.C.S., L.R.C.P.,
Superintendent of the Brown Institution,
University of London.
Sept. 15th, 1924.

COCAINE FOR EUTHANASIA.

To the Editor of THE LANCET.

SIR,—For several years I have used cocaine in the last stages of phthisis. Its benefits are so great and its use apparently so little known that a note on the subject may be justified. In the later stages of phthisis patients may be remarkably comfortable, especially if it is a pure tuberculous invasion with little or no added infection—or they may be carried off by a sudden hæmoptysis and be spared the suffering of the last phase. I have several times seen children dying of this disease remain calm and comparatively happy to the very end whose lungs have been riddled with disease and containing large cavities; they have slept a great deal and have appeared to suffer very little. Frequently, however, this is not the picture. The patient becomes apprehensive, restless, sleepless, he coughs much and brings up much phlegm, he is wasted to a shadow and his bony points pain him, his throat and larynx are frequently ulcerated, it hurts him to speak, to swallow, or even to breathe, coughing may become an agony to him and to others. Morphia may give immense comfort in some cases, but almost always when this is started a rapid deterioration takes place; in others less relief is given and there may be nausea and vomiting with flatulence, abdominal pain, and distension. The breathing becomes difficult with much rattling, and the relatives beg for something more to be done. It is just in such cases that I have found cocaine so useful. After its administration the patient becomes calmer, happier, the rattling often ceases, and almost a smile will come over the features. In an earlier stage than this, too, when death is long in coming and the patient seems to cling desperately to the tragic remnants of his life, cocaine will greatly relieve, and I would give it in preference to morphia or any opium derivative.

Cocaine should be given orally and by subcutaneous injection so that it may exert both its local and its general action. Enough must be given to produce a definite effect. I usually begin by giving gr. $\frac{1}{4}$ of the hydrochloride hypodermically, and gr. $\frac{1}{4}$ dissolved in some lemon juice and water with sugar to be sipped; both can be repeated as often as is desired at suitable intervals. The same treatment may be given in carcinoma of the stomach, and many other diseases where the patient dies slowly.

I am, Sir, yours faithfully,
F. G. CHANDLER, M.D. Camb., M.R.C.P. Lond.
Park-square West, N.W., Sept. 10th, 1924.

DIETETIC METABOLISM.

To the Editor of THE LANCET.

SIR,—In his interesting address in your issue of Sept. 13th, dealing with the remarkable capacity of man for metabolising almost any kind of food, Dr. C. J. Macalister suggests that dietetic variations of metabolism in man result from "recurrence, sometimes to carnivorous, sometimes towards a vegetarian type, and, if that be so, we must take it that there was a common stock from which both those types resulted." The adaptability of a living organism in its power of metabolism of other than its traditional and accustomed food is presumably a sound asset in favour of its survival. Some insects have this faculty in a high degree. Why should the female anopheles desert her native plant juices to suck mammalian blood at night? Is she in search of fresh hormones or what is the impulse? If, as Dr. Macalister suggests, there is a common stock for carnivorous and vegetarian feeders, the original ancestral form might well be a plant, for does not the sundew, tempted by the wealth of gnats in its native marsh, evolve a special method of ensnaring and a special faculty for digesting the said insects? But why stop at the sundew; have not some bacteria more or less a similar adaptability as regards metabolism? The carnivorous plant has always seemed to me to strengthen the argument in favour of a common origin of vegetable and animal life.

I am, Sir, yours faithfully,
DAVID WALSH
Bentinck-street, W., Sept. 14th, 1924.

SIR MALCOLM MORRIS MEMORIAL FUND.

THE hon. secretary of the committee sends the following supplementary list of subscribers to this Fund. The total to date is £476 14*s*. 8*d*.

Messrs. Bird and Bird, Mr. A. W. Byrne.
Prof. Winifred Cullis, D.Sc.
Girls' Boarding School Co., Limited.
Mr. Arthur Morris, Mr. A. Crichton Morris, Mr. Charles A. Morris, C.V.O.
National Association for the Prevention of Tuberculosis.
Sir Herbert Thompson, Mrs. Catherine Thursby.
Dr. Bertram Watson.

Further subscriptions will be gratefully acknowledged if forwarded to the Hon. Treasurers, "Sir Malcolm Morris Memorial Fund," at 12, Stratford-place, London, W. 1.

AN IRISH HAMPDEN.—Our Irish correspondent writes as follows:—Dr. J. A. O'Halloran was summoned before the Longford district court recently for failure to exhibit a licence duty disc on his motor-car. He said that he had not paid his motor tax because there were no roads in the county, and he asked that the case might be dismissed. A fine of five shillings was imposed. A few months ago a similar procedure took place, and Dr. O'Halloran, declining to pay the fine, was sent to goal. On his arrival at the gaol, at a distance of some 60 miles from his home, he paid the fine. The police authorities were put to the expense of driving him to gaol and back by motor. As they had difficulty in obtaining a car, it is said that they had to hire Dr. O'Halloran's own car for the journey. Subsequent to this incident some attempt was made by the Longford county council to make the roads fit for traffic, but owing to a labour dispute work was abandoned. The roads of the county have been neglected for several years and are said to be almost impassable.

Medical News.

OPENING OF THE MEDICAL SCHOOLS.—The following functions will be held in connexion with the opening of the undermentioned London Medical Schools:—

St. Bartholomew's Hospital.—Old students' dinner, Wednesday, Oct. 1st, in the great hall of the hospital.

Charing Cross Hospital.—Distribution of prizes by Sir Humphry Rolleston in the out-patients' hall of the hospital, Oct. 1st, at 3.30 P.M. Chairman: Dr. W. Cecil Bosanquet. Annual dinner of past and present students, in the Adelaide Gallery, Gatti's Restaurant, Strand, W.C. 2. Chairman: Mr. Charles Gibbs.

St. George's Hospital.—Prize distribution in large lecture theatre, Wednesday, Oct. 1st, at 3 P.M. Inaugural address by Sir Isambard Owen. Annual medical school dinner, Wednesday, Oct. 1st, at the New Hotel Metropole. Chairman: Sir Isambard Owen.

King's College Hospital.—Prize distribution, Wednesday, Oct. 1st, 2.30 P.M. Inaugural address by Sir David Ferrier. Chairman: Viscount Hambleden. Past and present students' dinner, Wednesday, Oct. 1st, at the Connaught Rooms, Great Queen-street, W.C. Chairman: Mr. Charles P. Childe.

London Hospital.—Old students' dinner, Wednesday, Oct. 1st, at the Trocadero Restaurant, Shaftesbury-avenue, W.C. Chairman: Prof. William Bulloch.

St. Mary's Hospital.—Past and present students' dinner, Monday, Oct. 6th, at the Connaught Rooms, Great Queen-street, W.C. Chairman: Dr. E. M. Callender.

Middlesex Hospital.—Prize distribution in the Queen's Hall, Wednesday, Oct. 1st, 3 P.M., by Lord Birkenhead. Inaugural address by Dr. Charles Porter on Some Aspects of Preventive Medicine. Annual dinner, Wednesday, Oct. 1st, at the Hotel Cecil. Chairman: Mr. G. Gordon-Taylor.

St. Thomas's Hospital.—The annual dinner of past and present students on Friday, Oct. 24th, at Prince's Restaurant, Piccadilly, W. Chairman: Dr. Seymour Taylor.

Westminster Hospital.—Introductory address by Mr. H. J. Waring on the Medical Man of the Future, in the board room of the hospital, Thursday, Oct. 2nd, at 3 P.M.

UNIVERSITY OF DURHAM.—At the opening of the winter session of the College of Medicine, Newcastle-upon-Tyne, on Oct. 6th, the address to the students will be delivered by Sir Thomas J. Horder, Bart.

LONDON (R.F.H.) SCHOOL OF MEDICINE FOR WOMEN.—This school will celebrate its jubilee in October, in connexion with which the following celebrations will be held: (1) A service of thanksgiving for the opportunities of training, work, and service, open to women in the last 50 years, at St. Paul's Cathedral, on Saturday, Oct. 25th, 2.30 P.M. (2) Dinner in the Guildhall on Friday, Oct. 24th. (3) An evening party at the medical school, Saturday, Oct. 25th.

An attractive pamphlet just issued by this school sets out briefly its history and summarises the progress achieved in the medical education of women since its foundation in 1874. At that time there were only two women in the Medical Register and 14 students at the school. To-day there are about 2000 women on the Register, of whom more than half were educated at this school. To celebrate the jubilee of the school it is hoped to endow chairs in physiology, pathology, and anatomy, to be named after the three great women pioneers in medicine, Elizabeth Blackwell, Elizabeth Garrett Anderson, and Sophia Jex-Blake, of whom charming portraits appear in the pamphlet. Donations to the Endowment Fund should be made payable to Sir Alan Garrett Anderson, hon. treasurer to the school, and addressed to the organising secretary of the Fund, Mrs. K. B. Duffus, 8, Hunter-street, London, W.C. 1.

QUEEN'S UNIVERSITY (BELFAST) CLUB, LONDON.—The second dinner of the club will be held in the Hotel Belgravia, Grosvenor-gardens, S.W., on Thursday, Oct. 9th, at 8 P.M. Open to members and to Queen's students and graduates desirous of becoming members. The charge for the dinner will be collected at the occasion. Those intending to be present are requested to notify, not later than Oct. 6th, the hon. secs., at 17, Wimpole-street, W. Previous to the dinner there will be held the annual meeting, beginning at 7.15 P.M.

SUMMER Time will cease on Sunday next, Sept. 21st, at 3 A.M., when the clock will be put back to 2 A.M. The hour 2–3 A.M. Summer Time will thus be followed by the hour 2–3 A.M. Greenwich Time. Last year Summer Time ceased on Sunday, Sept. 16th.

DONATIONS AND BEQUESTS.—The following, among other, bequests are made under the will of the late Mr. Samuel Woolland: £2000 to St. George's Hospital; £1000 to King Edward's Hospital Fund; £1000 to Fulham Cancer Hospital; £500 to the Royal Hospital at Winchester; £500 to the Royal Devon Hospital, Exeter; and £500 to Dr. Barnardo's Homes.

EXTENSION OF ABERGELE SANATORIUM.—The Manchester Public Health Committee have adopted a scheme to provide accommodation for 200 beds at the Abergele Sanatorium for surgical tuberculosis cases. At present there are only 10 beds for such cases at the sanatorium. The original scheme set out to provide 500 beds. The decision goes as a recommendation before the Finance Committee for approval or otherwise.

ROYAL DENTAL HOSPITAL OF LONDON.—A special Children's Department and an extension of the X ray Department are urgently needed to meet the requirements for the treatment of the poorer classes at the Royal Dental Hospital of London. The cost has been estimated at £3000, and in order to help in raising this sum a concert will be held at the Alhambra Theatre on Sunday evening, Oct. 5th, at 7 P.M. Sir Oswald Stoll has given the use of his theatre, and many well-known artists have promised to appear, including Mr. George Robey. The Prince of Wales, who is President of the hospital, has endorsed the appeal on its behalf in an autograph letter. Applications for tickets should be made to the hon. secretary, Lord Burnham's Appeal Fund, at the hospital, 32, Leicester-square, London, W.C. 2.

PROPOSED HOSPITAL FOR DISEASES OF THE HEART IN LIVERPOOL.—An influential meeting has been held in Liverpool to promote a movement for the establishment of a special hospital which would be entirely devoted to the study and treatment of diseases of the heart. The need for such a hospital for Liverpool and the surrounding district has been felt for a long time past by medical men. The meeting was addressed by Prof. Richard Caton, formerly professor of physiology, a former lord mayor of the city and pro-Chancellor of the University, also by Prof. J. M. Beattie, Sir James Paton, and others. It was unanimously resolved to take steps immediately to establish such a hospital. Suitable premises are available and substantial offers of financial assistance were announced and a general committee was nominated with Sir James Paton as chairman. The hospital will be the first of its kind in the district and will provide treatment for both in-patients and out-patients. In Liverpool alone something like 1500 persons are estimated as crippled from cardiac disease traceable to rheumatic fever.

COTTON SPINNERS' CANCER.—Information has been received by the Operative Cotton Spinners' Amalgamation that the Insurance Section of the Master Cotton Spinners' Federation has decided to accept and not to appeal against the "test" case decision at Ashton county court (THE LANCET, August 16th, p. 358) that epithelioma of the scrotum, from which a spinner had died, arose in the course of his employment and therefore falls within the scope of industrial diseases under the Workmen's Compensation Act. It is stated that the decision not to appeal was arrived at on legal advice. There are, according to the operatives' secretary, 100 cancer cases on his books awaiting decision. Much is hoped for—as a result of the publicity given to the case—in the matter of prevention of the disease. The Council of the Amalgamated Association of Operative Cotton Spinners and Twiners suggest that no worthier field in which to work can be found than for scientists by investigation to undertake the task of banishing this disease from all connexion with cotton-spinning. It is suggested that the trade itself, in conjunction with the medical profession, might investigate the cancer-producing properties of mineral oil and direct their efforts to the production of an oil innocent of such properties, or at least to the provision or improvement of preventive measures.

ARSENIC IN FOOD WRAPPERS IN SALFORD.—In his annual report of the borough of Salford for 1923 the borough analyst—Mr. J. D. Elsdon—states that when examining a sample of proprietary bread, it was discovered that the violet ink used for the printing of the wrapper contained appreciable quantities of arsenic. This led to the chemical examination of a large number of coloured wrappers and a number of coloured papers and inks used for printing. Of 51 sample wrapers nine contained an appreciable quantity of arsenic—the colours being two blue papers, five purple, and two green. The quantity of arsenic in one paper faced with a purple colour was about one-third of a grain per square foot of surface. Of nine different samples of printers' ink used for wrappers all were arsenic-free with the exception of one violet ink which contained about 10 per cent. of

arsenic calculated as arsenious oxide. The presence of the arsenic is due to the use of arsenic lakes in the colours from which the printing ink is made. It is alleged that by this means brighter colours are obtained. There is no real reason for their use. As to the milk sold in Salford, it compares favourably with that sold in other districts. With a standard—a lenient one—of more than 5 parts of sediment in 100,000—classified as "adulterated," no sample was so classified after the early months of the year. But the question of dirty milk is one of peculiar difficulty, as the retailer may quite easily remove the bulk of the visible dirt by filtration immediately before selling the milk. There may, however, be serious bacterial contamination, which is the usual concomitant of visible dirt. Out of 26 samples of jam taken and representative of the product of 20 different manufacturers, only seven, prepared by six different manufacturers, had been preserved with cane or beet sugar only. Eighteen samples from 13 vendors contained 8 to 20 per cent. of glucose syrup, while one sample contained as much as 35 per cent. of glucose syrup. Out of 32 samples of golden syrup 22 were found to be genuine golden syrup derived from cane or beet sugar products.

Appointments.

BARCLAY, J. H., M.D. Durh., has been appointed an additional Medical Referee under the Workmen's Compensation Act for the Districts of Gateshead, Hexham and Bellingham, &c.

CHAPMAN, DORA, M.B., Ch.B. Sheff., and ORD, J. W. E., M.D., C.M. McGill, Visiting Anæsthetists to the Jessop Hospital for Women.

GRAHAM, M. J., M.B., B.Ch. N.U.I., Medical Officer, Federated Malay States.

NEGUS, V. E., M.S., F.R.C.S., Junior Surgeon for Diseases of the Throat and Nose at King's College Hospital.

SELLARS, J. A., M.B., Ch.B. N.U.I., Hon. Assistant Physician, Blackburn Royal Infirmary.

THOMAS, B. M. G., M.R.C.S., L.R.C.P. Lond., Superintendent Medical Officer to the Pontypridd Board of Guardians at the Llwynypia Hospital.

WHITELAW, A. D., M.B., B.Ch., D.P.H. Camb., Temporary Assistant School Medical Officer in the Public Health Department of the City of Norwich.

WILLIAMS, H. M., M.R.C.S., L.R.C.P. Lond., D.P.H., Tuberculosis Physician to the County of Carmarthen.

Salford Royal Hospital: MCCAY, A. W., M.B., Ch.B. Edin., DAVIDSON, ALEX. W., M.B., Ch.B. Edin., House Surgeons; STOUT, A. J., M.B., Ch.B. Edin., Casualty House Surgeon.

Vacancies.

For further information refer to the advertisement columns.

Altrincham General Hospital, Cheshire.—H.S. £125.
Belgrave Hospital for Children, 1, Clapham-road, S.W.—H.P. and H.S. Each £100.
Bethnal Green Board of Guardians.—Asst. M.O. £400.
Birkenhead County Borough.—Asst. M.O. £450, res.
Bradford City.—Asst. Bacteriologist. £600.
Bradford Royal Infirmary.—Two H.S.'s and one H.P. Each £150.
Burton-upon-Trent County Borough.—Asst. M.O. £600.
Buxton, Derbyshire, Devonshire Hospital.—Asst. H.P. £150.
City of London Hospital for Diseases of the Heart, Victoria Park, E.—P.
Durham County Council, Maternity and Child Welfare.—Asst. Welfare M.O. £600.
Evelina Hospital for Children. Southwark, S.E.—H.P. £120.
Glasgow, Anderson College of Medicine, Dumbarton-road.—Chair of Surgery.
Hospital for Epilepsy and Paralysis, Maida Vale, W.—Med. Reg. £100.
Hospital for Sick Children, Great Ormond-street, W.C.—H.S. £50. Also H.P. and Asst. Cas. O. £50.
King's Lynn, West Norfolk and King's Lynn Hospital.—Asst. Res. M.O. £150.
Leeds City.—Asst. Clin. Tuberculosis O. £600.
Leicester Royal Infirmary.—H.S. £150.
Liverpool.—M.O.H. £1800.
London Lock Hospital, 91, Dean-street, W.—H.S. £200.
Manchester, St. Mary's Hospitals.—Four H.S.'s. Each £50.
Miller General Hospital for South-East London, Greenwich-road, S.E.—Hon. M.O. for Skin Dept. H.P. £125.
Ministry of Health.—Three M.O.'s. £600.
National Hospital for Diseases of the Heart, Westmoreland-street, W.—Phys. to Out-patients.
Northampton General Hospital.—Hon. P.
Nottingham General Dispensary.—Res. S. £250.
Pietermaritzburg, S. Africa, Grey's Hospital.—H.S. £400.
Plymouth, South Devon and East Cornwall Hospital.—H.S. and H.P. £100 and £50 respectively. Also Asst. H.S. £50.
Portsmouth, St. Mary's Infirmary, &c.—Third Asst. Res. M.O. £250.
Prince of Wales's General Hospital, Tottenham, N.—H.S.'s, H.P., Each £150. Also Jun. H.S. and H.P. Each £110.
Queen's Hospital for Children, Hackney-road, E.—H.S. £100. Two H.P.'s, Cas. H.S. Each £100. Also P. in charge of Skin Dept.
Rhondda Urban District Council.—Asst. Sch. M.O. £600.
Richmond, Surrey, Royal Hospital.—Asst. H.S. £100.
Royal Chest Hospital, City-road, E.C.—P.
Royal Ear Hospital, Dean-street, Soho.—Reg. £50.
Royal Free Hospital, Gray's Inn-road, W.C.—Med. Reg.
Royal Naval Medical Service.—Surg. Lieuts. 25s. per day.
Royal Westminster Ophthalmic Hospital, King William-street, Strand, W.C.—Asst. H.S.
Seamen's Hospital Society, Greenwich.—H.S. for Albert Dock Hospital. Also H.P. and H.S. at Dreadnought Hospital. Each £150.
Shanghai Municipal Council, Public Health Department.—Asst. Path. £1250.
South London Hospital for Women, Clapham Common, S.W.—H.P. and three H.S.'s. Each £50. Clin. Asst. £1 1s. per attendance.
University College Hospital, Gower-street, W.C.—Res. M.O. £150.
Wakefield, West Riding Mental Hospital.—Jun. Asst. M.O. £400.
West End Hospital for Nervous Diseases, Regent's Park, N.W.—H.P. £150.
Western Ophthalmic Hospital, Marylebone-road, N.W.—Sen. and Jun. Non. Res. H.S. £150 and £100 respectively.
Westminster Hospital, S.W.—Hon. Asst. Administrator of Anæsthetics.

The Chief Inspector of Factories, Home Office, London, S.W., announces the following vacant appointments:—St. Albans, Herts; Westerham, Kent; Kidwelly, Carmarthen.

Births, Marriages, and Deaths.

BIRTHS.

HEAF.—On Sept. 13th, at Hertford Hill, Warwick, the wife of Frederick Heaf, M.D., of a son.

LEWIN.—On Sept. 9th, at a London nursing home, to the wife of Dr. George Lewin, of 1, Haling Park-road, S. Croydon—a daughter.

MILLIGAN.—On Sept. 9th, the wife of Dr. Hubert Milligan, Cliftonville, Lytham, of a daughter.

NEELY.—On Sept. 13th, at Vernon House, Lee-road, Blackheath, the wife of Dr. Guy Neely, of a son.

WESTERMAN.—On Sept. 6th, at Snow-hill, London, E.C., the wife of Dr. Arthur Westerman, of a son.

MARRIAGES.

BERRY—ELKINS.—On Sept. 6th, at Watford Parish Church, Dr. Douglas Haycrast Berry, to Mary (Mollie), only daughter of Dr. and Mrs. F. A. Elkins, of Watford.

CORSI—DOYLE.—On Sept. 4th, at St. Paul's, Knightsbridge, Henry Corsi, F.R.C.S., to Margaret Gleaves Doyle, daughter of the late William Gleaves Doyle, F.R.G.S., and Mrs. Doyle, of Walcote, Leamington Spa.

HICKSON—WHITELOCK.—On Sept. 10th, at Whitchurch, Eric Blanford Hickson, M.R.C.S., L.R.C.P., to Joan Frances Whitelock, M.B., B.S., elder daughter of Mr. and Mrs. A. R. Whitelock, of Underwood, Whitchurch.

HILTON-PARRY—WILLIAMS.—On Sept. 10th, at St. Pancras, Dr. William Hilton-Parry, M.C., M.B., B.Ch., of Carnarvon, to Martha Williams, of Merthyr Tydvil.

KEARNEY—GRAY.—On Sept. 2nd, at The Oratory Brompton-road, W., Dr. James Kearney to Kathleen Hilda Gray, daughter of Mr. and Mrs. Frederick E. Gray, of Leyton, Essex.

QUINET—WILLCOX.—On Sept. 9th, at the Parish Church, Solihull, Warwickshire, Paul Gustave Desiré Quinet, M.B., Ch.B., M.R.C.S., L.R.C.P., to Doris Elizabeth Willcox, M.B., Ch.B., B.Sc.

SCOTT—NEEDELL.—On Sept. 12th, at the Parish Church, Hendon, James Bethune Scott, M.C., M.B., Ch.B. Vict., to Leila, only daughter of Mr. and Mrs. T. J. Needell, of Sunningfields-road, Hendon.

DEATHS.

ATTERBURY.—On July 18th, at Monowai, Graham-street, Whangarei, N.Z., Walter Atterbury, M.D., late of Finchley, aged 72.

BIDDLE.—On Sept. 14th, at Wortley, Manorgate-road, Kingston Hill, Daniel Biddle, M.R.C.S., L.S.A., aged 84.

POWER.—On Sept. 7th, at Borrisoleigh, Co. Tipperary, Dr. Joseph Power.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

THE Manager of THE LANCET would like to purchase copies of the issue of Feb. 2nd, 1924, for which subscribers may have no further use. He will be pleased to pay 1s. each for them. Such copies should be addressed to him at 423, Strand, London, W.C. 2.

Medical News.

OPENING OF THE MEDICAL SCHOOLS.—The following functions will be held in connexion with the opening of the undermentioned London Medical Schools:—

St. Bartholomew's Hospital.—Old students' dinner, Wednesday, Oct. 1st, in the great hall of the hospital.

Charing Cross Hospital.—Distribution of prizes by Sir Humphry Rolleston in the out-patients' hall of the hospital, Oct. 1st, at 3.30 P.M. Chairman: Dr. W. Cecil Bosanquet. Annual dinner of past and present students, in the Adelaide Gallery, Gatti's Restaurant, Strand, W.C. 2. Chairman: Mr. Charles Gibbs.

St. George's Hospital.—Prize distribution in large lecture theatre, Wednesday, Oct. 1st, at 3 P.M. Inaugural address by Sir Isambard Owen. Annual medical school dinner, Wednesday, Oct. 1st, at the New Hotel Metropole. Chairman: Sir Isambard Owen.

King's College Hospital.—Prize distribution, Wednesday, Oct. 1st, 2.30 P.M. Inaugural address by Sir David Ferrier. Chairman: Viscount Hambleden. Past and present students' dinner, Wednesday, Oct. 1st, at the Connaught Rooms, Great Queen-street, W.C. Chairman: Mr. Charles P. Childe.

London Hospital.—Old students' dinner, Wednesday, Oct. 1st, at the Trocadero Restaurant, Shaftesbury-avenue, W.C. Chairman: Prof. William Bulloch.

St. Mary's Hospital.—Past and present students' dinner, Monday, Oct. 6th, at the Connaught Rooms, Great Queen-street, W.C. Chairman: Dr. E. M. Callender.

Middlesex Hospital.—Prize distribution in the Queen's Hall, Wednesday, Oct. 1st, 3 P.M., by Lord Birkenhead. Inaugural address by Dr. Charles Porter on Some Aspects of Preventive Medicine. Annual dinner, Wednesday, Oct. 1st, at the Hotel Cecil. Chairman: Mr. G. Gordon-Taylor.

St. Thomas's Hospital.—The annual dinner of past and present students on Friday, Oct. 24th, at Prince's Restaurant, Piccadilly, W. Chairman: Dr. Seymour Taylor.

Westminster Hospital.—Introductory address by Mr. H. J. Waring on the Medical Man of the Future, in the board room of the hospital, Thursday, Oct. 2nd, at 3 P.M.

UNIVERSITY OF DURHAM.—At the opening of the winter session of the College of Medicine, Newcastle-upon-Tyne, on Oct. 6th, the address to the students will be delivered by Sir Thomas J. Horder, Bart.

LONDON (R.F.H.) SCHOOL OF MEDICINE FOR WOMEN.—This school will celebrate its jubilee in October, in connexion with which the following celebrations will be held: (1) A service of thanksgiving for the opportunities of training, work, and service, open to women in the last 50 years, at St. Paul's Cathedral, on Saturday, Oct. 25th, 2.30 P.M. (2) Dinner in the Guildhall on Friday, Oct. 24th. (3) An evening party at the medical school, Saturday, Oct. 25th.

An attractive pamphlet just issued by this school sets out briefly its history and summarises the progress achieved in the medical education of women since its foundation in 1874. At that time there were only two women in the Medical Register and 14 students at the school. To-day there are about 2000 women on the Register, of whom more than half were educated at this school. To celebrate the jubilee of the school it is hoped to endow chairs in physiology, pathology, and anatomy, to be named after the three great women pioneers in medicine, Elizabeth Blackwell, Elizabeth Garrett Anderson, and Sophia Jex-Blake, of whom charming portraits appear in the pamphlet. Donations to the Endowment Fund should be made payable to Sir Alan Garrett Anderson, hon. treasurer to the school, and addressed to the organising secretary of the Fund, Mrs. K. B. Duffus, 8, Hunter-street, London, W.C. 1.

QUEEN'S UNIVERSITY (BELFAST) CLUB, LONDON.—The second dinner of the club will be held in the Hotel Belgravia, Grosvenor-gardens, S.W., on Thursday, Oct. 9th, at 8 P.M. Open to members and to Queen's students and graduates desirous of becoming members. The charge for the dinner will be collected at the occasion. Those intending to be present are requested to notify, not later than Oct. 6th, the hon. secs., at 17, Wimpole-street, W. Pre- the dinner there will be held the annual meeting, at 7.15 P.M.

Time will cease on Sunday next, Sept. 21st, when the clock will be put back to 2 A.M. The A.M. Summer Time will thus be followed by the 3 A.M. Greenwich Time. Last year Summer Time on Sunday, Sept. 16th.

DONATIONS AND BEQUESTS.—The following, among other, bequests are made under the will of the late Mr. Samuel Woolland: £2000 to St. George's Hospital; £1000 to King Edward's Hospital Fund; £1000 to Fulham Cancer Hospital; £500 to the Royal Hospital at Winchester; £500 to the Royal Devon Hospital, Exeter; and £500 to Dr. Barnardo's Homes.

EXTENSION OF ABERGELE SANATORIUM.—The Manchester Public Health Committee have adopted a scheme to provide accommodation for 200 beds at the Abergele Sanatorium for surgical tuberculosis cases. At present there are only 10 beds for such cases at the sanatorium. The original scheme set out to provide 500 beds. The decision goes as a recommendation before the Finance Committee for approval or otherwise.

ROYAL DENTAL HOSPITAL OF LONDON.—A special Children's Department and an extension of the X ray Department are urgently needed to meet the requirements for the treatment of the poorer classes at the Royal Dental Hospital of London. The cost has been estimated at £3000, and in order to help in raising this sum a concert will be held at the Alhambra Theatre on Sunday evening, Oct. 5th, at 7 P.M. Sir Oswald Stoll has given the use of his theatre, and many well-known artists have promised to appear, including Mr. George Robey. The Prince of Wales, who is President of the hospital, has endorsed the appeal on its behalf in an autograph letter. Applications for tickets should be made to the hon. secretary, Lord Burnham's Appeal Fund, at the hospital, 32, Leicester-square, London, W.C. 2.

PROPOSED HOSPITAL FOR DISEASES OF THE HEART IN LIVERPOOL.—An influential meeting has been held in Liverpool to promote a movement for the establishment of a special hospital which would be entirely devoted to the study and treatment of diseases of the heart. The need for such a hospital for Liverpool and the surrounding district has been felt for a long time past by medical men. The meeting was addressed by Prof. Richard Caton, formerly professor of physiology, a former lord mayor of the city and pro-Chancellor of the University, also by Prof. J. M. Beattie, Sir James Paton, and others. It was unanimously resolved to take steps immediately to establish such a hospital. Suitable premises are available and substantial offers of financial assistance were announced and a general committee was nominated with Sir James Paton as chairman. The hospital will be the first of its kind in the district and will provide treatment for both in-patients and out-patients. In Liverpool alone something like 1500 persons are estimated as crippled from cardiac disease traceable to rheumatic fever.

COTTON SPINNERS' CANCER.—Information has been received by the Operative Cotton Spinners' Amalgamation that the Insurance Section of the Master Cotton Spinners' Federation has decided to accept and not to appeal against the "test" case decision at Ashton county court (THE LANCET, August 16th, p. 358) that epithelioma of the scrotum, from which a spinner had died, arose in the course of his employment and therefore falls within the scope of industrial diseases under the Workmen's Compensation Act. It is stated that the decision not to appeal was arrived at on legal advice. There are, according to the operatives' secretary, 100 cancer cases on his books awaiting decision. Much is hoped for—as a result of the publicity given to the case—in the matter of prevention of the disease. The Council of the Amalgamated Association of Operative Cotton Spinners and Twiners suggest that no worthier field in which to work can be found than for scientists by investigation to undertake the task of banishing this disease from all connexion with cotton-spinning. It is suggested that the trade itself, in conjunction with the medical profession, might investigate the cancer-producing properties of mineral oil and direct their efforts to the production of an oil innocent of such properties, or at least to the provision or improvement of preventive measures.

ARSENIC IN FOOD WRAPPERS IN SALFORD.—In his annual report of the borough of Salford for 1923 the borough analyst—Mr. J. D. Elsdon—states that when examining a sample of proprietary bread, it was discovered that the violet ink used for the printing of the wrapper contained appreciable quantities of arsenic. This led to the chemical examination of a large number of coloured wrappers and a number of coloured papers and inks used for printing. Of 51 sample wrapers nine contained an appreciable quantity of arsenic—the colours being two blue papers, five purple, and two green. The quantity of arsenic in one paper faced with a purple colour was about one-third of a grain per square foot of surface. Of nine different samples of printers' ink used for wrappers all were arsenic-free with the exception of one violet ink which contained about 10 per cent. of

arsenic calculated as arsenious oxide. The presence of the arsenic is due to the use of arsenic lakes in the colours from which the printing ink is made. It is alleged that by this means brighter colours are obtained. There is no real reason for their use. As to the milk sold in Salford, it compares favourably with that sold in other districts. With a standard—a lenient one—of more than 5 parts of sediment in 100,000—classified as "adulterated," no sample was so classified after the early months of the year. But the question of dirty milk is one of peculiar difficulty, as the retailer may quite easily remove the bulk of the visible dirt by filtration immediately before selling the milk. There may, however, be serious bacterial contamination, which is the usual concomitant of visible dirt. Out of 26 samples of jam taken and representative of the product of 20 different manufacturers, only seven, prepared by six different manufacturers, had been preserved with cane or beet sugar only. Eighteen samples from 13 vendors contained 8 to 20 per cent. of glucose syrup, while one sample contained as much as 35 per cent. of glucose syrup. Out of 32 samples of golden syrup 22 were found to be genuine golden syrup derived from cane or beet sugar products.

Appointments.

BARCLAY, J. H., M.D. Durh., has been appointed an additional Medical Referee under the Workmen's Compensation Act for the Districts of Gateshead, Hexham and Bellingham, &c.

CHAPMAN, DORA, M.B., Ch.B. Sheff., and ORD, J. W. E., M.D., C.M. McGill, Visiting Anæsthetists to the Jessop Hospital for Women.

GRAHAM, M. J., M.B., B.Ch. N.U.I., Medical Officer, Federated Malay States.

NEGUS, V. E., M.S., F.R.C.S., Junior Surgeon for Diseases of the Throat and Nose at King's College Hospital.

SELLARS, J. A., M.B., Ch.B. N.U.I., Hon. Assistant Physician, Blackburn Royal Infirmary.

THOMAS, B. M. G., M.R.C.S., L.R.C.P. Lond., Superintendent Medical Officer to the Pontypridd Board of Guardians at the Llwynypia Hospital.

WHITELAW, A. D., M.B., B.Ch., D.P.H. Camb., Temporary Assistant School Medical Officer in the Public Health Department of the City of Norwich.

WILLIAMS, H. M., M.R.C.S., L.R.C.P. Lond., D.P.H., Tuberculosis Physician to the County of Carmarthen.

Salford Royal Hospital: MCCAY, A. W., M.B., Ch.B. Edin., DAVIDSON, ALEX. W., M.B., Ch.B. Edin., House Surgeons: STOUT, A. J., M.B., Ch.B. Edin., Casualty House Surgeon.

Vacancies.

For further information refer to the advertisement columns.

Altrincham General Hospital, Cheshire.—H.S. £125.

Belgrave Hospital for Children, 1, Clapham-road, S.W.—H.P. and H.S. Each £100.

Bethnal Green Board of Guardians.—Asst. M.O. £400.

Birkenhead County Borough.—Asst. M.O. £450, res.

Bradford City.—Asst. Bacteriologist. £600.

Bradford Royal Infirmary.—Two H.S.'s and one H.P. Each £150.

Burton-upon-Trent County Borough.—Asst. M.O. £600.

Buxton, Derbyshire, Devonshire Hospital.—Asst. H.P. £150.

City of London Hospital for Diseases of the Heart, Victoria Park, E.—P.

Durham County Council, Maternity and Child Welfare.—Asst. Welfare M.O. £600.

Evelina Hospital for Children, Southwark, S.E.—H.P. £120.

Hospital for Epilepsy and Paralysis, Maida Vale, W.—Med. Reg. £100.

Hospital for Sick Children, Great Ormond-street, W.C.—H.S. £50. Also H.P. and Asst. Cas. O. £50.

King's Lynn, West Norfolk and King's Lynn Hospital.—Asst. Res. M.O. £150.

Leeds City.—Asst. Clin. Tuberculosis O. £600.

Leicester Royal Infirmary.—H.S. £150.

Liverpool.—M.O.H. £1800.

London Lock Hospital, 91, Dean-street, W.—H.S. £200.

Manchester, St. Mary's Hospitals.—Four H.S.'s. Each £50.

Miller General Hospital for South-East London, Greenwich-road, S.E.—Hon. M.O. for Skin Dept. H.P. £125.

Ministry of Health.—Three M.O.'s. £600.

National Hospital for Diseases of the Heart, Westmoreland-street, W.—Phys. to Out-patients.

Northampton General Hospital.—Hon. P.

Nottingham General Dispensary.—Res. S. £250.

Pietermaritzburg, S. Africa, Grey's Hospital.—H.S. £400.

Plymouth, South Devon and East Cornwall Hospital.—H.S. and H.P. £100 and £50 respectively. Also Asst. H.S. £50.

Portsmouth, St. Mary's Infirmary, &c.—Third Asst. Res. M.O. £250.

Prince of Wales's General Hospital, Tottenham, N.—H.S.'s, H.P., Each £150. Also Jun. H.S. and H.P. Each £110.

Queen's Hospital for Children, Hackney-road, E.—H.S. £100. Two H.P.'s, Cas. H.S. Each £100. Also P. in charge of Skin Dept.

Rhondda Urban District Council.—Asst. Sch. M.O. £600.

Richmond, Surrey, Royal Hospital.—Asst. H.S. £100.

Royal Chest Hospital, City-road, E.C.—P.

Royal Ear Hospital, Dean-street, Soho.—Reg. £50.

Royal Free Hospital, Gray's Inn-road, W.C.—Med. Reg.

Royal Naval Medical Service.—Surg. Lieuts. 25s. per day.

Royal Westminster Ophthalmic Hospital, King William-street, Strand, W.C.—Asst. H.S.

Seamen's Hospital Society, Greenwich.—H.S. for Albert Dock Hospital. Also H.P. and H.S. at Dreadnought Hospital. Each £150.

Shanghai Municipal Council, Public Health Department.—Asst. Path. £1250.

South London Hospital for Women, Clapham Common, S.W.—H.P. and three H.S.'s. Each £50. Clin. Asst. £1 1s. per attendance.

University College Hospital, Gower-street, W.C.—Res. M.O. £150.

Wakefield, West Riding Mental Hospital.—Jun. Asst. M.O. £400.

West End Hospital for Nervous Diseases, Regent's Park, N.W.—H.P. £150.

Western Ophthalmic Hospital, Marylebone-road, N.W.—Sen. and Jun. Non. Res. H.S. £150 and £100 respectively.

Westminster Hospital, S.W.—Hon. Asst. Administrator of Anæsthetics.

The Chief Inspector of Factories, Home Office, London, S.W., announces the following vacant appointments:—St. Albans, Herts; Westerham, Kent; Kidwelly, Carmarthen.

Births, Marriages, and Deaths.

BIRTHS.

HEAF.—On Sept. 13th, at Hertford Hill, Warwick, the wife of Frederick Heaf, M.D., of a son.

LEWIN.—On Sept. 9th, at a London nursing home; to the wife of Dr. George Lewin, of 1, Haling Park-road, S. Croydon—a daughter.

MILLIGAN.—On Sept. 9th, the wife of Dr. Hubert Milligan, Cliftonville, Lytham, of a daughter.

NEELY.—On Sept. 13th, at Vernon House, Lee-road, Blackheath, the wife of Dr. Guy Neely, of a son.

WESTERMAN.—On Sept. 6th, at Snow-hill, London, E.C., the wife of Dr. Arthur Westerman, of a son.

MARRIAGES.

BERRY—ELKINS.—On Sept. 6th, at Watford Parish Church, Dr. Douglas Haycrast Berry, to Mary (Mollie), only daughter of Dr. and Mrs. F. A. Elkins, of Watford.

CORSI—DOYLE.—On Sept. 4th, at St. Paul's, Knightsbridge, Henry Corsi, F.R.C.S., to Margaret Gleaves Doyle, daughter of the late William Gleaves Doyle, F.R.G.S., and Mrs. Doyle, of Walcote, Leamington Spa.

HICKSON—WHITELOCK.—On Sept. 10th, at Whitchurch, Eric Blanford Hickson, M.R.C.S., L.R.C.P., to Joan Frances Whitelock, M.B., B.S., elder daughter of Mr. and Mrs. A. R. Whitelock, of Underwood, Whitchurch.

HILTON-PARRY—WILLIAMS.—On Sept. 10th, at St. Pancras, Dr. William Hilton-Parry, M.C., M.B., B.Ch., of Carnarvon, to Martha Williams, of Merthyr Tydvil.

KEARNEY—GRAY.—On Sept. 2nd, at The Oratory Brompton-road, W., Dr. James Kearney to Kathleen Hilda Gray, daughter of Mr. and Mrs. Frederick E. Gray, of Leyton, Essex.

QUINET—WILLCOX.—On Sept. 9th, at the Parish Church, Solihull, Warwickshire, Paul Gustave Desiré Quinet, M.B., Ch.B., M.R.C.S., L.R.C.P., to Doris Elizabeth Willcox, M.B., Ch.B., B.Sc.

SCOTT—NEEDELL.—On Sept. 12th, at the Parish Church, Hendon, James Bethune Scott, M.C., M.B., Ch.B. Vict., to Leila, only daughter of Mr. and Mrs. T. J. Needell, of Sunningfields-road, Hendon.

DEATHS.

ATTERBURY.—On July 18th, at Monowai, Graham-street, Whangarei, N.Z., Walter Atterbury, M.D., late of Finchley, aged 72.

BIDDLE.—On Sept. 14th, at Wortley, Manorgate-road, Kingston Hill, Daniel Biddle, M.R.C.S., L.S.A., aged 84.

POWER.—On Sept. 7th, at Borrisoleigh, Co. Tipperary, Dr. Joseph Power.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

THE Manager of THE LANCET would like to purchase copies of the issue of Feb. 2nd, 1924, for which subscribers may have no further use. He will be pleased to pay 1s. each for them. Such copies should be addressed to him at 423, Strand, London, W.C. 2.

Medical News.

Opening of the Medical Schools.—The following functions will be held in connexion with the opening of the undermentioned London Medical Schools:—

St. Bartholomew's Hospital.—Old students' dinner, Wednesday, Oct. 1st, in the great hall of the hospital.

Charing Cross Hospital.—Distribution of prizes by Sir Humphry Rolleston in the out-patients' hall of the hospital, Oct. 1st, at 3.30 P.M. Chairman: Dr. W. Cecil Bosanquet. Annual dinner of past and present students, in the Adelaide Gallery, Gatti's Restaurant, Strand, W.C. 2. Chairman: Mr. Charles Gibbs.

St. George's Hospital.—Prize distribution in large lecture theatre, Wednesday, Oct. 1st, at 3 P.M. Inaugural address by Sir Isambard Owen. Annual medical school dinner, Wednesday, Oct. 1st, at the New Hotel Metropole. Chairman: Sir Isambard Owen.

King's College Hospital.—Prize distribution, Wednesday, Oct. 1st, 2.30 P.M. Inaugural address by Sir David Ferrier. Chairman: Viscount Hambleden. Past and present students' dinner, Wednesday, Oct. 1st, at the Connaught Rooms, Great Queen-street, W.C. Chairman: Mr. Charles P. Childe.

London Hospital.—Old students' dinner, Wednesday, Oct. 1st, at the Trocadero Restaurant, Shaftesbury-avenue, W.C. Chairman: Prof. William Bulloch.

St. Mary's Hospital.—Past and present students' dinner, Monday, Oct. 6th, at the Connaught Rooms, Great Queen-street, W.C. Chairman: Dr. E. M. Callender.

Middlesex Hospital.—Prize distribution in the Queen's Hall, Wednesday, Oct. 1st, 3 P.M., by Lord Birkenhead. Inaugural address by Dr. Charles Porter on Some Aspects of Preventive Medicine. Annual dinner, Wednesday, Oct. 1st, at the Hotel Cecil. Chairman: Mr. G. Gordon-Taylor.

St. Thomas's Hospital.—The annual dinner of past and present students on Friday, Oct. 24th, at Prince's Restaurant, Piccadilly, W. Chairman: Dr. Seymour Taylor.

Westminster Hospital.—Introductory address by Mr. H. J. Waring on the Medical Man of the Future, in the board room of the hospital, Thursday, Oct. 2nd, at 3 P.M.

University of Durham.—At the opening of the winter session of the College of Medicine, Newcastle-upon-Tyne, on Oct. 6th, the address to the students will be delivered by Sir Thomas J. Horder, Bart.

London (R.F.H.) School of Medicine for Women.—This school will celebrate its jubilee in October, in connexion with which the following celebrations will be held: (1) A service of thanksgiving for the opportunities of training, work, and service, open to women in the last 50 years, at St. Paul's Cathedral, on Saturday, Oct. 25th, 2.30 P.M. (2) Dinner in the Guildhall on Friday, Oct. 24th. (3) An evening party at the medical school, Saturday, Oct. 25th.

An attractive pamphlet just issued by this school sets out briefly its history and summarises the progress achieved in the medical education of women since its foundation in 1874. At that time there were only two women in the Medical Register and 14 students at the school. To-day there are about 2000 women on the Register, of whom more than half were educated at this school. To celebrate the jubilee of the school it is hoped to endow chairs in physiology, pathology, and anatomy, to be named after the three great women pioneers in medicine, Elizabeth Blackwell, Elizabeth Garrett Anderson, and Sophia Jex-Blake, of whom charming portraits appear in the pamphlet. Donations to the Endowment Fund should be made payable to Sir Alan Garrett Anderson, hon. treasurer to the school, and addressed to the organising secretary of the Fund, Mrs. K. B. Duffus, 8, Hunter-street, London, W.C. 1.

Queen's University (Belfast) Club, London.—The second dinner of the club will be held in the Hotel Belgravia, Grosvenor-gardens, S.W., on Thursday, Oct. 9th, at 8 P.M. Open to members and to Queen's students and graduates desirous of becoming members. The charge for the dinner will be collected at the occasion. Those intending to be present are requested to notify, not later than Oct. 6th, the hon. secs., at 17, Wimpole-street, W. Previous to the dinner there will be held the annual meeting, beginning at 7.15 P.M.

Summer Time will cease on Sunday next, Sept. 21st, at 3 A.M., when the clock will be put back to 2 A.M. The hour 2–3 A.M. Summer Time will thus be followed by the hour 2–3 A.M. Greenwich Time. Last year Summer Time ceased on Sunday, Sept. 16th.

Donations and Bequests.—The following, among other, bequests are made under the will of the late Mr. Samuel Woolland: £2000 to St. George's Hospital; £1000 to King Edward's Hospital Fund; £1000 to Fulham Cancer Hospital; £500 to the Royal Hospital at Winchester; £500 to the Royal Devon Hospital, Exeter; and £500 to Dr. Barnardo's Homes.

Extension of Abergele Sanatorium.—The Manchester Public Health Committee have adopted a scheme to provide accommodation for 200 beds at the Abergele Sanatorium for surgical tuberculosis cases. At present there are only 10 beds for such cases at the sanatorium. The original scheme set out to provide 500 beds. The decision goes as a recommendation before the Finance Committee for approval or otherwise.

Royal Dental Hospital of London.—A special Children's Department and an extension of the X ray Department are urgently needed to meet the requirements for the treatment of the poorer classes at the Royal Dental Hospital of London. The cost has been estimated at £3000, and in order to help in raising this sum a concert will be held at the Alhambra Theatre on Sunday evening, Oct. 5th, at 7 P.M. Sir Oswald Stoll has given the use of his theatre, and many well-known artists have promised to appear, including Mr. George Robey. The Prince of Wales, who is President of the hospital, has endorsed the appeal on its behalf in an autograph letter. Applications for tickets should be made to the hon. secretary, Lord Burnham's Appeal Fund, at the hospital, 32, Leicester-square, London, W.C. 2.

Proposed Hospital for Diseases of the Heart in Liverpool.—An influential meeting has been held in Liverpool to promote a movement for the establishment of a special hospital which would be entirely devoted to the study and treatment of diseases of the heart. The need for such a hospital for Liverpool and the surrounding district has been felt for a long time past by medical men. The meeting was addressed by Prof. Richard Caton, formerly professor of physiology, a former lord mayor of the city and pro-Chancellor of the University, also by Prof. J. M. Beattie, Sir James Paton, and others. It was unanimously resolved to take steps immediately to establish such a hospital. Suitable premises are available and substantial offers of financial assistance were announced and a general committee was nominated with Sir James Paton as chairman. The hospital will be the first of its kind in the district and will provide treatment for both in-patients and out-patients. In Liverpool alone something like 1500 persons are estimated as crippled from cardiac disease traceable to rheumatic fever.

Cotton Spinners' Cancer.—Information has been received by the Operative Cotton Spinners' Amalgamation that the Insurance Section of the Master Cotton Spinners' Federation has decided to accept and not to appeal against the "test" case decision at Ashton county court (The Lancet, August 16th, p. 358) that epithelioma of the scrotum, from which a spinner had died, arose in the course of his employment and therefore falls within the scope of industrial diseases under the Workmen's Compensation Act. It is stated that the decision not to appeal was arrived at on legal advice. There are, according to the operatives' secretary, 100 cancer cases on his books awaiting decision. Much is hoped for—as a result of the publicity given to the case—in the matter of prevention of the disease. The Council of the Amalgamated Association of Operative Cotton Spinners and Twiners suggest that no worthier field in which to work can be found than for scientists by investigation to undertake the task of banishing this disease from all connexion with cotton-spinning. It is suggested that the trade itself, in conjunction with the medical profession, might investigate the cancer-producing properties of mineral oil and direct their efforts to the production of an oil innocent of such properties, or at least to the provision or improvement of preventive measures.

Arsenic in Food Wrappers in Salford.—In his annual report of the borough of Salford for 1923 the borough analyst—Mr. J. D. Elsdon—states that when examining a sample of proprietary bread, it was discovered that the violet ink used for the printing of the wrapper contained appreciable quantities of arsenic. This led to the chemical examination of a large number of coloured wrappers and a number of coloured papers and inks used for printing. Of 51 sample wrappers nine contained an appreciable quantity of arsenic—the colours being two blue papers, five purple, and two green. The quantity of arsenic in one paper faced with a purple colour was about one-third of a grain per square foot of surface. Of nine different samples of printers' ink used for wrappers all were arsenic-free with the exception of one violet ink which contained about 10 per cent. of

arsenic calculated as arsenious oxide. The presence of the arsenic is due to the use of arsenic lakes in the colours from which the printing ink is made. It is alleged that by this means brighter colours are obtained. There is no real reason for their use. As to the milk sold in Salford, it compares favourably with that sold in other districts. With a standard—a lenient one—of more than 5 parts of sediment in 100,000—classified as "adulterated," no sample was so classified after the early months of the year. But the question of dirty milk is one of peculiar difficulty, as the retailer may quite easily remove the bulk of the visible dirt by filtration immediately before selling the milk. There may, however, be serious bacterial contamination, which is the usual concomitant of visible dirt. Out of 26 samples of jam taken and representative of the product of 20 different manufacturers, only seven, prepared by six different manufacturers, had been preserved with cane or beet sugar only. Eighteen samples from 13 vendors contained 8 to 20 per cent. of glucose syrup, while one sample contained as much as 35 per cent. of glucose syrup. Out of 32 samples of golden syrup 22 were found to be genuine golden syrup derived from cane or beet sugar products.

Appointments.

BARCLAY, J. H., M.D. Durh., has been appointed an additional Medical Referee under the Workmen's Compensation Act for the Districts of Gateshead, Hexham and Bellingham, &c.

CHAPMAN, DORA, M.B., Ch.B. Sheff., and ORD, J. W. E., M.D., C.M. McGill, Visiting Anæsthetists to the Jessop Hospital for Women.

GRAHAM, M. J., M.B., B.Ch. N.U.I., Medical Officer, Federated Malay States.

NEGUS, V. E., M.S., F.R.C.S., Junior Surgeon for Diseases of the Throat and Nose at King's College Hospital.

SELLARS, J. A., M.B., Ch.B. N.U.I., Hon. Assistant Physician, Blackburn Royal Infirmary.

THOMAS, B. M. G., M.R.C.S., L.R.C.P. Lond., Superintendent Medical Officer to the Pontypridd Board of Guardians at the Llwynypia Hospital.

WHITELAW, A. D., M.B., B.Ch., D.P.H. Camb., Temporary Assistant School Medical Officer in the Public Health Department of the City of Norwich.

WILLIAMS, H. M., M.R.C.S., L.R.C.P. Lond., D.P.H., Tuberculosis Physician to the County of Carmarthen.

Salford Royal Hospital: MCCAY, A. W., M.B., Ch.B. Edin., DAVIDSON, ALEX. W., M.B., Ch.B. Edin., House Surgeons; STOUT, A. J., M.B., Ch.B. Edin., Casualty House Surgeon.

Vacancies.

For further information refer to the advertisement columns.

Altrincham General Hospital, Cheshire.—H.S. £125.

Belgrave Hospital for Children, 1, Clapham-road, S.W.—H.P. and H.S. Each £100.

Bethnal Green Board of Guardians.—Asst. M.O. £400.

Birkenhead County Borough.—Asst. M.O. £450, res.

Bradford City.—Asst. Bacteriologist. £600.

Bradford Royal Infirmary.—Two H.S.'s and one H.P. Each £150.

Burton-upon-Trent County Borough.—Asst. M.O. £600.

Buxton, Derbyshire, Devonshire Hospital.—Asst. H.P. £150.

City of London Hospital for Diseases of the Heart, Victoria Park, E.—P.

Durham County Council, Maternity and Child Welfare.—Asst. Welfare M.O. £600.

Evelina Hospital for Children, Southwark, S.E.—H.P. £120.

Glasgow, Anderson College of Medicine, Dumbarton-road.—Chair of Surgery.

Hospital for Epilepsy and Paralysis, Maida Vale, W.—Med. Reg. £100.

Hospital for Sick Children, Great Ormond-street, W.C.—H.S. £50. Also H.P. and Asst. Cas. O. £50.

King's Lynn, West Norfolk and King's Lynn Hospital.—Asst. Res. M.O. £150.

Leeds City.—Asst. Clin. Tuberculosis O. £600.

Leicester Royal Infirmary.—H.S. £150.

Liverpool.—M.O.H. £1800.

London Lock Hospital, 91, Dean-street, W.—H.S. £200.

Manchester, St. Mary's Hospitals.—Four H.S.'s. Each £50.

Miller General Hospital for South-East London, Greenwich-road, S.E.—Hon. M.O. for Skin Dept. H.P. £125.

Ministry of Health.—Three M.O.'s. £600.

National Hospital for Diseases of the Heart, Westmoreland-street, W.—Phys. to Out-patients.

Northampton General Hospital.—Hon. P.

Nottingham General Dispensary.—Res. S. £250.

Pietermaritzburg, S. Africa, Grey's Hospital.—H.S. £400.

Plymouth, South Devon and East Cornwall Hospital.—H.S. and H.P. £100 and £50 respectively. Also Asst. H.S. £50.

Portsmouth, St. Mary's Infirmary, &c.—Third Asst. Res. M.O. £250.

Prince of Wales's General Hospital, Tottenham, N.—H.S.'s, H.P., Each £150. Also Jun. H.S. and H.P. Each £110.

Queen's Hospital for Children, Hackney-road, E.—H.S. £100. Two H.P.'s, Cas. H.S. Each £100. Also P. in charge of Skin Dept.

Rhondda Urban District Council.—Asst. Sch. M.O. £600.

Richmond, Surrey, Royal Hospital.—Asst. H.S. £100.

Royal Chest Hospital, City-road, E.C.—P.

Royal Ear Hospital, Dean-street, Soho.—Reg. £50.

Royal Free Hospital, Gray's Inn-road, W.C.—Med. Reg.

Royal Naval Medical Service.—Surg. Lieuts. 25s. per day.

Royal Westminster Ophthalmic Hospital, King William-street, Strand, W.C.—Asst. H.S.

Seamen's Hospital Society, Greenwich.—H.S. for Albert Dock Hospital. Also H.P. and H.S. at Dreadnought Hospital. Each £150.

Shanghai Municipal Council, Public Health Department.—Asst. Path. £1250.

South London Hospital for Women, Clapham Common, S.W.—H.P. and three H.S.'s. Each £50. Clin. Asst. £1 1s. per attendance.

University College Hospital, Gower-street, W.C.—Res. M.O. £150.

Wakefield, West Riding Mental Hospital.—Jun. Asst. M.O. £400.

West End Hospital for Nervous Diseases, Regent's Park, N.W.—H.P. £150.

Western Ophthalmic Hospital, Marylebone-road, N.W.—Sen. and Jun. Non. Res. H.S. £150 and £100 respectively.

Westminster Hospital, S.W.—Hon. Asst. Administrator of Anæsthetics.

The Chief Inspector of Factories, Home Office, London, S.W., announces the following vacant appointments:—St. Albans, Herts; Westerham, Kent; Kidwelly, Carmarthen.

Births, Marriages, and Deaths.

BIRTHS.

HEAF.—On Sept. 13th, at Hertford Hill, Warwick, the wife of Frederick Heaf, M.D., of a son.

LEWIN.—On Sept. 9th, at a London nursing home; to the wife of Dr. George Lewin, of 1, Haling Park-road, S. Croydon—a daughter.

MILLIGAN.—On Sept. 9th, the wife of Dr. Hubert Milligan, Cliftonville, Lytham, of a daughter.

NEELY.—On Sept. 13th, at Vernon House, Lee-road, Blackheath, the wife of Dr. Guy Neely, of a son.

WESTERMAN.—On Sept. 6th, at Snow-hill, London, E.C., the wife of Dr. Arthur Westerman, of a son.

MARRIAGES.

BERRY—ELKINS.—On Sept. 6th, at Watford Parish Church, Dr. Douglas Haycrast Berry, to Mary (Mollie), only daughter of Dr. and Mrs. F. A. Elkins, of Watford.

CORSI—DOYLE.—On Sept. 4th, at St. Paul's, Knightsbridge, Henry Corsi, F.R.C.S., to Margaret Gleaves Doyle, daughter of the late William Gleaves Doyle, F.R.G.S., and Mrs. Doyle, of Walcote, Leamington Spa.

HICKSON—WHITELOCK.—On Sept. 10th, at Whitchurch, Eric Blanford Hickson, M.R.C.S., L.R.C.P., to Joan Frances Whitelock, M.B., B.S., elder daughter of Mr. and Mrs. A. R. Whitelock, of Underwood, Whitchurch.

HILTON-PARRY—WILLIAMS.—On Sept. 10th, at St. Pancras, Dr. William Hilton-Parry, M.C., M.B., B.Ch., of Carnarvon, to Martha Williams, of Merthyr Tydvil.

KEARNEY—GRAY.—On Sept. 2nd, at The Oratory Brompton-road, W., Dr. James Kearney to Kathleen Hilda Gray, daughter of Mr. and Mrs. Frederick E. Gray, of Leyton, Essex.

QUINET—WILLCOX.—On Sept. 9th, at the Parish Church, Solihull, Warwickshire, Paul Gustave Desiré Quinet, M.B., Ch.B., M.R.C.S., L.R.C.P., to Doris Elizabeth Willcox, M.B., Ch.B., B.Sc.

SCOTT—NEEDELL.—On Sept. 12th, at the Parish Church, Hendon, James Bethune Scott, M.C., M.B., Ch.B. Vict., to Leila, only daughter of Mr. and Mrs. T. J. Needell, of Sunningfields-road, Hendon.

DEATHS.

ATTERBURY.—On July 18th, at Monowai, Graham-street, Whangarei, N.Z., Walter Atterbury, M.D., late of Finchley, aged 72.

BIDDLE.—On Sept. 14th, at Wortley, Manorgate-road, Kingston Hill, Daniel Biddle, M.R.C.S., L.S.A., aged 84.

POWER.—On Sept. 7th, at Borrisoleigh, Co. Tipperary, Dr. Joseph Power.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

THE Manager of THE LANCET would like to purchase copies of the issue of Feb. 2nd, 1924, for which subscribers may have no further use. He will be pleased to pay 1s. each for them. Such copies should be addressed to him at 423, Strand, London, W.C. 2.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, London, W.

MONDAY, Sept. 22nd, to SATURDAY, Sept. 27th.—ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, Charing Cross. Clinical instruction every afternoon from 2 o'clock. Wed., 5 P.M., Mr. Gimblett: Clinical Demonstration on Common Affections of the Eye. Thurs., 5 P.M., Mr. Morgan: Fundus Class. Fri., 10 A.M., Mr. Hine: Methods of Examination.—INFANTS HOSPITAL, Vincent-square, Westminster. Mon., 2 P.M., Dr. W. E. Robinson: O.P., Chest Cases. 3 P.M., The Hon. Noel Olivier Richards, M.D.: Demonstration, Nursery Hygiene and Clothing. 4 P.M., Dr. Donald Paterson: Congenital Heart Disease, with cases. Tues., 2 P.M., Dr. Eric Pritchard: O.P., Cases of Tuberculosis and Congenital Syphilis. 3 P.M., Dr. Amy Hodgson: Demonstration, Diet from 1 to 5 years. Dr. Bertram Shires: Lectures and Demonstrations: Diagnosis by X rays. Wed., 2 P.M., Dr. Helen Mackay: O.P., Selected Cases. 3 P.M., Dr. Eric Pritchard: Demonstration, Dried Milk. 4 P.M., Dr. Helen Mackay: Pyrexia and its Clinical Investigation. Thurs., 2 P.M., Dr. Donald Paterson: O.P., Special Cases. 3 P.M., Dr. Eric Pritchard: Demonstration, Patent Foods. 4 P.M., Mr. M. S. Mayou: Lecture, The Prophylaxis of Certain Eye Diseases. Fri., 2 P.M., Dr. Eric Pritchard and Members of the Staff: Round Table Consultation. 4 P.M., Dr. Helen Mackay: Lecture, Pyrexia and its Clinical Investigation. Sat., 2 P.M., Visit to the Nursery Training School, Hampstead Garden Suburb, and to Home for Blind Babies, Sunshine House, Chorley Wood.—WESTMINSTER HOSPITAL, S.W. Mon., 10.30 A.M., Mr. W. Spencer: Oral Sepsis. 11.30 A.M., Dr. Hildred Carlill: Clinical Demonstration on Medical Cases. 2 P.M., Mr. A. Evans: Wards and Cases. 4.30 P.M., Dr. Stott: Lecture, Diagnosis of Heart Diseases. Tues., 10.30 A.M., Mr. A. D. Griffith: Ophthalmic Operations. 11.30 A.M., Dr. de Souza: Hormones and Disease. 2 P.M., Mr. W. Turner: Operations. 4.30 P.M., Mr. B. Henry: Dental Radiograms and their Interpretation. Wed., 10.30 A.M., Dr. Braxton Hicks: Pathology, Importance of Detail in Collection of Laboratory Samples by the Practitioner. 2 P.M., Mr. A. Evans: Operations. 4.30 P.M., Dr. E. S. Dore: Demonstration, Skin Cases. Thurs., 10.30 A.M., Mr. G. C. Chubb: Demonstration, Nose, Throat, and Ear Cases. 11.30 A.M., Mr. Stanford Cole: Colostomy. 2 P.M., Mr. Rock Carling: Operations. 4.30 P.M., Dr. A. Stott: Treatment of Heart Diseases. Fri., 10.30 A.M., Dr. A. S. Woodwarke: The Insulin Treatment of Diabetes. 11.30 A.M., Mr. A. Goodwin: Retroversion. 2 P.M., Mr. W. Turner: Operations. 4.30 P.M., Dr. E. S. Worrall: Lecture on High-Frequency Currents and Diathermy. Sat., 11–12.30, Camberwell House, Dr. H. J. Norman: Clinical Demonstration, Mental Disease.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

MONDAY, Sept. 22nd.—12 noon, Mr. Simmonds: Applied Anatomy. 2 P.M., Mr. Addison: Surgical Wards. 2 P.M., Mr. Bishop Harman: Eye Dept.

TUESDAY.—11 A.M., Mr. Endean: Venereal Diseases. 12 noon, Dr. Burrell: Chest Cases. 2 P.M., Mr. Sinclair: Surgical Out-patients.

WEDNESDAY.—10 A.M., Dr. Saunders: Medical Diseases of Children. 2 P.M., Dr. Owen: Medical Out-patients. 2 P.M., Dr. Pernet: Skin Dept.

THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Dept. 2 P.M., Mr. Simmonds: Surgical Out-patients. 2 P.M., Mr. MacDonald: Genito-Urinary Dept.

FRIDAY.—12 noon, Surgical Registrar: Surgical Pathology. 2 P.M., Dr. Burrell: Medical Out-patients. 2 P.M., Mr. Vlasto: Throat, Nose, and Ear Dept.

SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy. 10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations on Throat, Nose, and Ear.

Daily 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

Notes, Comments, and Abstracts.

GOVERNMENT MEDICAL SERVICES IN INDIA.

BY MAJOR-GENERAL SIR PATRICK HEHIR, K.C.I.E., C.B., I.M.S. (RET.).

THE Medical Services in India have been the subject of many inquiries, and are dealt with in the corresponding Blue-books, the Report of the Lee Commission being the latest of these. A ratification of the recommendations contained in that Report as a whole is being called for. The Commissioners themselves, probably prompted by the strained conditions they found during their comprehensive and invaluable investigation, also urge an early decision regarding their proposals. While there is full sympathy with this desire, as far as the medical services are concerned, wisdom may lie in making haste slowly, for here no less than a revolution is contemplated.

For purposes of clearness I set out much that is necessarily known to many readers, but the situation demands a more or less full story.

The Report proposes the introduction of far-reaching changes in the All-India Services on the civil side, particularly in the superior services of Provincial Governments. Medical men are specially concerned with the proposed replacement of the Indian Medical Service by the Royal Army Medical Corps (India), and the creation of a civil medical service on a provincial basis. These are changes which should not be made without much deliberation as to their immediate and ultimate effect on medical work in India. That some modification in the Government medical services in India was necessary has been obvious for the last half century. The desirability of some form of amalgamation of the R.A.M.C. and I.M.S. was prominently brought out in the late war when officers trained in two separate organisations had to work in unison in the field.

It has been contended by Indian politicians and others that in civilised countries under a constitutional government the civil and military services are separate, and they consider that this should be the case in India. It has not been sufficiently recognised that the conditions of the medical profession are complicated in India by circumstances not necessarily present in other countries: there are few grounds for comparison with countries which have a homogeneous population in which the civil medical services can be readily adjusted to meet war requirements, and in which there is only one system of medicine practised.

Schemes for Reform.

A brief review of various Commissions and Committees on this subject should elucidate the present position.

Royal Commission on Public Services (1912–15).—This Commission carried out its inquiry from 1912 to 1915, but on account of the war its Report was not published until 1917, by which time it had become obsolete in many respects. The Report stated: "From inquiries which we have made we are satisfied that under the existing arrangements the civil medical work of the country (India) has hitherto been economically and satisfactorily performed."

Montagu-Chelmsford Reform Scheme (1919).—The reform scheme gave birth to the Government of India Act (1919) which forms the present constitution of India. It introduced vast changes and authorised much wider employment of Indians in the administrative and executive work of the country. The result as far as the medical services of the country is concerned has been to introduce in our medical schools a feeling of uncertainty and insecurity which must be reflected in the numbers of Europeans anxious to undertake a medical career in India.

Verney-Lovett Committee (1919).—This Committee proposed the creation of a unified service, to be known as the Indian Medical Corps, which would discharge all the medical duties in India, civil and military, and would be composed of the existing I.M.S., to which would be added, initially, volunteers from the R.A.M.C., men selected by the Secretary of State for India from the temporary I.M.S. and R.A.M.C. officers that were then serving, and candidates from the medical schools in Great Britain and Ireland to be selected by half-yearly competitive examination in which Indian candidates with Indian qualifications would be given special facilities to compete. This Indian Medical Corps was to incorporate all members of the Indian Medical Department (assistant surgeons and sub-assistant surgeons). Retirement of officers with gratuities after fixed periods of service anterior to pension period was an important and special feature of the scheme. Most of the recommendations of the Verney-Lovett Committee were adopted, but the creation of an Indian Medical Corps, which was the soul of the scheme, was turned down. At the time this was the best all-round solution for a unified medical service; it seemed to meet both the military and civil medical requirements of the country, especially the latter. There are many who still look upon it as the best scheme from all points of view.

Esher Committee (1919–20).—The Esher Committee stated: "We consider that the Verney-Lovett report puts forward the only feasible scheme for a unified medical service, but we feel unable to support that scheme because it would, after the first selection had been made, permanently exclude the R.A.M.C. from India. Such exclusion would adversely affect, especially at the present time, both the large body of British troops in India, whose health has hitherto been so admirably safeguarded by the R.A.M.C., and the service itself, which would be shut out from the wide field of medical experience that India affords. . . . The amalgamation of the I.M.S. and R.A.M.C. is in present conditions impracticable." It suggested improvements in existing conditions, but advised the continuation of the two services as separate units.

Lee Commission (1924).—Regarding the medical services the Lee Commission recommends:—

"(*a*) That while all concessions granted to the All-India Services should be extended to the existing members of the I.M.S. in civil employ, no attempt should be made to perpetuate that service as at present constituted.

"(*b*) That, contrary to the recommendations of the Verney-Lovett Committee that the I.M.S. should be developed into a new Indian Medical Corps which should absorb the R.A.M.C. in India, the medical needs of both the British and Indian armies in India should be provided for, in future, by the R.A.M.C. (India) which should absorb the I.M.S."; the R.A.M.C. (India) is to be formed from the R.A.M.C., ad hoc. Of the British medical men in the civil medical service one-half should be reserved for British officers to be seconded from the R.A.M.C. (India), the remainder being obtained through the (R.A.M.C.) competitive examination held in London. If the number required to complete the authorised establishment cannot be obtained by the local government through the Public Service Commission, the deficiency is to be made up so far as possible by increased seconding of officers from the R.A.M.C. (India), the transfers from the R.A.M.C. (India) to civil would form the war reserve for the army in India.

The Report states: This scheme "is capable of adaptation to meet the requirements of the provinces for a separate medical service and to provide the necessary nucleus of British officers which we regard as vital to the needs and contentment of British civil servants in India." From this it would appear that the Lee Commission found the clamour for an independent civil medical service on a provincial basis so strong that it could no longer be resisted.

The R.A.M.C. (India): The Military Side.

In general terms it may be stated that the formation of the R.A.M.C. (India) would be a re-creation of the I.M.S. in another form. It would, however, be under one organisation, adopt one system of training, its officers would have identical aims, and its position would be one of considerable strength; the old jealousies, friction, and conflicting interests would disappear. It may confidently be expected that a good number of well-qualified young men of the home medical schools desiring an Indian career will join this service with the view to obtaining professional work in the provinces, and when political opinion has settled down they will have a full and useful life. The number of R.A.M.C. (India) officers eligible for civil employ will largely depend upon what the Commander-in-Chief in India declares to be the minimum of medical officers he requires as a war reserve. This is a sound scheme for a military-medical service for India, and if it is made to include the assistant surgeon branch of the Indian Medical Department (there does not appear any adequate reason why it should not) it can hardly be criticised, but it will be costly.

The Civil Side.

The proposals made for the civil side appear to be less satisfactory. The Public Service Commission to be brought into being is the only security that candidates for the essentially civil medical service will have. It is possible that prospective British candidates will not be satisfied with such guarantees as regards security of tenure of appointment as the Public Service Commission can give, while they would readily have sought employment in an *Imperial* Civil Medical Service such as was suggested by Lieut.-General Sir Charles Burtchaell in his note on the Verney-Lovett Committee's Report (App. II., Lee Commission's Report). It is probable that there will be few candidates for an essentially provincial service. This means that in course of time all the civil medical officers not provided through the R.A.M.C. (India) would be Indians, the speed of the Indianisation of the civil medical service being probably much more rapid than is expected in the Report. Many with long Indian experience consider it premature to reduce the number of European medical officers in civil employ. The Lee Commission's proposal would seem to introduce on the civil side too great a change, one for which the indigenous medical profession is not ready. The Report, however, admits the possibility of the adoption of its recommendations lowering the efficiency of the administrations, but considers that the risk should be taken in order to facilitate the logical evolution of the constitutional changes implied in the Government of India Act.

In the medical colleges and the hospitals connected with them the clinical chairs are reserved for provincial medical officers, if suitable men are available; it is possible, even probable, that within the ensuing ten years all these chairs will be filled by Indians. The scientific and research posts are to be thrown open to all candidates, but as there may be little or no competition from the home universities it is likely that these also, in course of time, will be filled by Indians.

Medical Education in India.

This is so supremely important a subject that its general supervision should remain in the hands of the Imperial Government. It is open to many forms of abuse. Some central professional authority should keep a firm hand in regulating and maintaining the standard of that education. The mere fact that the Central Government is the real controlling authority will itself have a potent effect in keeping up a uniformity of standard of the required dimensions. It cannot be too forcibly insisted upon that medical education in India is still in process of development. The standard of medical education will decline in direct ratio to the extent to which European medical men are eliminated from the teaching appointments. If all the medical professorships were handed over to the Indian medical men in the provinces the General Medical Council of Great Britain would soon be obliged to cease to recognise Indian medical qualifications altogether. India should be able to provide the sons and daughters of the soil with a first-class medical education; they should not be obliged to come to Great Britain for it. When colleges and hospitals thoroughly equipped in educational material, and entirely staffed by Indians can give this education, the task of the European professor will have been completed. Many years will elapse before this can happen. It is probable that to obtain a certain percentage of the best European medical men available provincial governments will offer large emoluments, especially in connexion with the teaching appointments in the medical colleges and college hospitals, and some of these will be accepted. These may initially take the form of short contracts. Such an arrangement will be extravagant and unsatisfactory. It will take some time for a new-comer to reach a maximum degree of usefulness, and when he becomes most efficient he may, for one reason or another, elect to relinquish his appointment.

The Indian Medical Service.

In the second half of the nineteenth century the Indian Medical Service was *facile princeps*, the best medical service in the world—a veritable *corps d'élite*. During that period it was recruited from the pick of the medical schools of the United Kingdom. The origin of that service in point of time practically coincides with that of our occupation of India, and it has a splendid record of devoted service to the people of that country. In late years the British candidate appointed to the I.M.S. went out to India with prospects greatly depreciated, chiefly on account of the hostility to the British element; this has been revealed in the debates of the Central and Provincial Legislative Assemblies, on political platforms, and in the press controlled by Indians. In the capital towns of several provinces there has been a boycott of I.M.S. Europeans from consulting practice, and European civil surgeons have found patients prevented from attending their hospitals by men specially posted for that purpose. It is only by recognising that all this is part of a political programme that it has been bearable.

The hope of obtaining civil employment has always been the determining factor that induced men to enter the I.M.S. But the civil side alone would not have lured the best young men from home. The military side has added to the fascination of the I.M.S. It was the combination of a commission in His Majesty's Army with the prospect of field service, together with unrivalled opportunities for a professional life, that attracted the superior men of the home medical schools to the I.M.S. India on the civil side requires the highest class of European medical men now more than ever if the fine edifice of Western medical science, which has been created by over a century of effort on the part of the I.M.S., is not to topple to the ground.

Medical Treatment of Europeans.

One great cause of anxiety among European officials in India is the decreasing possibility of obtaining medical advice for themselves and their families from doctors of their own race. This is a matter of the greatest importance if European officers are to be contented. Growing Indianisation and the large areas to be covered has made the provision of such medical advice more and more difficult. The solution of this problem by the Lee Commission seems the best possible one in the circumstances. Districts or provinces are to be grouped and a British medical officer (civil or military) is to be posted to one station in each group. The station should be easy of access. In stations where there is no British medical officer facilities are to be given for either the officer or his family to visit the medical officer or vice versâ, Government meeting the travelling expenses. Where only military medical officers are present they are to be made use of and receive the usual fees. Hospital accommodation for sick European officials and their families at the group station and in the larger hill stations would complete this solution of the problem. It may be that from the present situation in India the proposal of the Lee Commission is the only way to ensure there being a sufficient number of European medical men in India to give advice to the Europeans in the country. It is presumed that the Government is bound within certain limits to afford medical attendance to all its European employees by medical men of their own race. Neglect to do this will cause such dissatisfaction as will materially affect recruitment of Europeans for all the services. Endeavours should be made to strike the happy mean of maintaining a sufficient number of European medical officers for our military and civil services in both peace and war, and yet deal in an absolutely just and sympathetic way with the legitimate aspirations of Indians to hold their due place in the medical organisation of the country.

Action Required, but not Haste.

If the Lee Commission's proposals regarding the medical services are to be carried out it is suggested that it be done gradually. Whilst undue haste in arriving at decisions is to be deprecated, it is earnestly hoped that the Report will not share the fate of some of its predecessors by becoming obsolete before any action is taken. Political opinion is shifting rapidly in India. Many serious questions hang on the decisions, settlement of some of which is long overdue.

JAIL ADMINISTRATION IN BENGAL.[1]

THE report for 1922 commences with a short account of two mutinies that occurred in the Presidency Jail, one in April and the other in October, 1922. In the first outbreak, which was of a serious nature, 9 convicts were killed and 47 wounded, while of the jail staff one warder died from injuries received, and 36 other warders or members of the staff were injured; 14 convicts escaped, of whom 7 were subsequently captured, and the jute and oil godowns were set on fire and seriously damaged, with considerable loss of raw materials and manufactured articles. Several hundreds of political prisoners were admitted in December, 1921, and at one time there were 1400 non-coöperator and Khilaphat prisoners, in addition to the ordinary jail population. "It can thus be seen that it was impossible for the staff to cope with the enormous amount of extra work entailed. It was a time of great stress and anxiety for all concerned; the jailer and his assistants were never off duty, and great credit is due to their patience with this troublesome class of prisoner. Intense propaganda was spread among the Indian warders and seriously affected their morale." Fire had to be opened on the convicts, and troops called in to aid the jail staff. The second mutiny was not so serious, and there was no loss of life. Lieut.-Colonel W. G. Hamilton, I.M.S., Officiating Inspector-General of Prisons, Bengal, who presents this report, refers to the expression of opinion by Government of India "that non-criminal lunatics should not be committed to jail, and that criminal lunatics should not be detained in jails a day longer than is necessary." In future non-criminal lunatics belonging to Calcutta and its suburbs will be accommodated in the Bhawanipur Mental Hospital; and those belonging to Dacca and Murshidabad districts will be sent to the mental hospitals in those districts instead of to jail. "In other districts the jails must continue to take in non-criminal lunatics, a most undesirable practice." Government have sanctioned the creation of a new class—"special class prisoners," to be certified as such "on account of status, education, and character of the offence," who will be accorded special treatment at the Berhampore district jail.

The total admissions to jail, including transfers, numbered 84,985 in 1922 and the average daily strength was 15,220, as compared with 83,366 and 14,661 in 1921; the convicts numbered 43,945 admissions (including transfers), the average present being 12,512; the corresponding figures for 1921 were 42,998 and 12,211. Of the total number of convicts admitted (28,655, as stated in para. 8), 58·3 per cent. were Mahommedans, 38·7 Hindus, the remainder including Christians, Buddhists, and Jains. The Bengal Children's Act was passed during the year under review, making imprisonment illegal for children under 14 years of age, and for young persons under 16, unless under exceptional circumstances. "Unfortunately, this Act cannot be enforced owing to lack of funds for providing the necessary institutions and probation officers." The total earnings of all the jails (except the Presidency jail, the accounts of which are not forthcoming) amounted to Rs.6,81,199, giving an average per head (of those sentenced to labour) of Rs.56·6. At the Juvenile jail at Alipore, the chief industry is the manufacture of quinine tablets; 905,685 treatment tubes (each containing 20 4-grain tablets) were sold, realising a profit of Rs.1,64,207. The net earnings of the district jails amounted to Rs.2,70,926, as compared with Rs.3,45,156 in 1921. Of this total the Juvenile jail gave the best results, with an average earnings per head by those employed of Rs.1862.

In regard to the health of the prisoners of all classes in 1922, the daily average population being 15,220 (of whom 12,511 were convicts), the admissions to hospital averaged 1230 per 1000, the constantly sick 43·0, and the deaths 18·7; the daily average sick ratio was lower than in any of the four years preceding, during which it had fallen satisfactorily from 57·4 in 1918 to 45·1 in 1921. Among convicted prisoners in 1922 these three ratios were 1249·5, 31·2, and 19·1 respectively. The death-rate (18·7) was higher than in the previous year (16·0), but lower than in the years 1918–19–20, when it had been 21·3, 22·9, and 20·9, respectively; although not so low as in 1921 it was better than the five-year average, and Lieut.-Colonel Hamilton considers it to be "quite satisfactory." There were 35 cases of cholera and 16 deaths, as compared with only one case (not fatal) in 1921; at Mymensingh in Dacca division there were 22 cases and 10 deaths; and at the Presidency jail, Calcutta, there were 9 cases and 5 deaths; here the infection was probably introduced by "carriers," as the disease was prevalent in the city at the same time. The common jail scourge, dysentery, caused 1510 admissions to hospital and 39 deaths among convicted prisoners, giving ratios of 120·6 and 3·1 per 1000 respectively, as compared with 106·6 and 2·5 in the previous year. The admission ratios were highest at Chittagong (602·6) and Barisal (474·4), and the death-rate at Jalpaiguri was 15·7; it is noteworthy that in 17 jails not a single death from this cause occurred among convicted prisoners, a striking testimony to their general sanitation and good management. In conclusion, Lieut.-Colonel Hamilton states that "all jailers had a trying time during the past year, and much praise is due to them for the loyal way in which they carried out their arduous duties."

---

A HELP TO TRAVELLING PHOTOGRAPHERS.

To tourists or travellers devoid of the convenience of a dark room, the "tabloid" desensitiser just put on the market by Messrs. Burroughs, Wellcome and Co. will be of service. The action of the desensitiser is to remove a great proportion of the sensitiveness of the emulsion without destroying the latent image created by exposure. With its use, after one minute's treatment in the dark, development can be completed by candle-light, or (in the shadow of the body) in a room lighted by gas or electric light; and even ultra-sensitive and colour plates can be developed with care by candle-light or dim gas-light. Panchromatic plates can be developed in a comfortable light. The desensitiser is issued in cartons of 25.

COMPENSATED DISABILITY.

WE have received from Messrs. W. R. Grossmith, Ltd. (12, Burleigh-street, Strand, London, W.C.2), a small pamphlet entitled "Nature Reproduced," in which are recorded some of the achievements of amputees who use the artificial limbs of this well-known firm. The merits of the "Anglesey" pattern artificial leg, which has been in use in this country since the middle of the last century, have long been known, but have been perhaps unduly overshadowed by the successes achieved by American types, especially those modified and improved by British makers during the war. Nevertheless, the fact remains that "Anglesey" legs, when properly made and fitted, can be as light as or even lighter than any other limb upon the market, whether made of metal, leather, wood, or composition, and their wearers have achieved notable successes in walking competitions and have taken part in all manner of sports and occupations. Recognition of the merits of any one type of limb by no means implies condemnation of other types.

Some Principles
OF
TREATMENT IN THE
RADIO-THERAPEUTICS OF CANCER.

BY FRANCIS HERNAMAN-JOHNSON,
M.D. ABERD.,
RADIOLOGIST TO THE FRENCH HOSPITAL, LONDON; MEDICAL OFFICER IN CHARGE, X RAY AND ELECTRICAL DEPARTMENT, CROYDON GENERAL HOSPITAL, ETC.

I.

THE present would seem to be a suitable time to try to set forth some guiding principles for the radiotherapy of malignant disease. As often happens, it appeared much easier in earlier days to formulate such principles than is the case to-day. Ten years ago the simple faith of most of us, myself included, was that the secret of progress lay in finding means to irradiate a deep-seated tumour thoroughly without damage to the skin. For my own part, I always recognised that the tissues surrounding a growth played an important part in its cure, and that it was possible to stimulate them by X rays, while at the same time depressing the tumour cells. Nevertheless, I believed that the harder the ray the better for both purposes.

Let us consider this view and examine how far it will carry us.

The introduction into this country of X rays generated at 200–230,000 volts, filtered through 10 millimetres of aluminium or its equivalent, dates back to the year 1921; and at a discussion at the Royal Society of Medicine in March last (1924) we got a representative summary of the results. Disappointment was the keynote of most of the remarks. Many speakers frankly stated that the new methods were in their opinion no better than the old. I do not forget that the "new rays" were applied according to a new technique, and that it may be argued that this technique does not make the best use of them. But I have, myself, had an opportunity of comparing the results of rays generated at 160 kilo-volts with those from a 230 kilo-volt machine, the same technique being used in each case. I had been able to discover no difference in the results in pelvic cancer—the same temporary miracles being accomplished in both cases; and in breast cases it appeared to me that the longer wave-length had a rather better effect. A four-day dosage was adopted in both instances, and the filtration was the same. The skin dose was also equal, but the "depth dose," of course, reached a less intensity in the one case than in the other. Very similar results were reported from America in 1921 before European apparatus arrived there, a four-day dosage being used at 120 to 130 kilo-volts. It would be, of course, idle to deny that for pelvic growths a hard filtered ray is necessary, and there must be a limit below which efficiency falls rapidly. But, despite theoretical considerations regarding "percentage depth dose," it is doubtful if the very high voltages show any advantages in actual practice.

When we come to breast cancer, the Erlangen results are admitted to be disappointing, and curious attempts—which, to the writer's mind, savour of imitative magic—have been made to turn them artificially into deep-seated tumours by wax blocks—in order that the conditions present in uterine carcinoma may be reproduced! Now, it is a well-known fact that in former days excellent effects have been obtained in carcinoma mammæ by rays generated at about 100 to 120 kilo-volts with 2 millimetres of aluminium as a filter. Clinical evidence does not support the view that in breast cancer there are any advantages in very hard rays.

Sometimes one's faith in the whole principle of penetration receives a jar. Some years ago an old lady of 70 was sent to me suffering from a large ulcerating epithelioma of the thigh. She had had radium treatment, which at first did good, but finally seemed to make things worse. The friends were averse also to X rays, which, rightly, they regarded as closely akin to radium. More as a placebo than for any other reason, I decided to try rays from a tungsten arc. The thickened edge rapidly flattened out, and the whole ulcerated surface healed within a few weeks. There was already secondary mischief within the pelvis, and the patient died shortly afterwards—killed, her friends firmly believe to this day, by the unwise proceeding of closing her ulcer! This by the way. The point of interest is that the epitheliomatous tissue must have been at least a quarter of an inch in thickness, and therefore for the most part impenetrable to ultra-violet rays. Yet they caused it to disappear where radium had only produced irritaiton.

I made a statement in 1916, I think, to the effect that ultra-violet rays could not benefit exophthalmic goitre "because they had practically no penetration"; and one sees similar statements to-day. But I now cry peccavi. The only proof we can have that any therapeutic measure is of benefit is that in the first place improvement follows treatment in a large percentage of cases—a percentage high enough to exclude the possibility of what we call coincidence. This broad fact must first be established. Then suggestion must be excluded, and, so far as possible, extraneous physical factors. By the latter I mean, for example, fresh air, when one is estimating the benefits of natural sunlight, and change of scene and diet when considering the effects of mineral waters. When every care has been taken along such lines, we should never say that it is impossible that such and such measures should have effected a cure, because this appears to be incompatible with some *present* scientific belief. Over and over again clinical evidence has been discounted on such grounds, while later investigation has furnished a simple explanation. When chemical analysis had reached great exactitude certain mineral waters, which were said to lose some of their virtue when bottled, were examined, and it was found that their chemical composition remained constant for years; it was, therefore, declared impossible that their effects, if any, should differ from those produced at the actual spa. Later, it was shown these waters are at their source charged with radium emanation (*niton*); and this, of course, disintegrates within a few days.

At the present time one often sees it denied that certain very high dilutions of drugs can produce any physiological effect "because most of the doses would not contain a single molecule of the substance." But already some active substances are admitted to be potent in fractions so minute that only a few years ago the possibility of their producing any physiological effect would have been laughed at. The clinical test is alone of value. There is no difference between post hoc and propter hoc except a numerical one. All the above is somewhat of a digression, but it is vitally necessary in a subject such as radiology, in which the study of physical science is essential, that we should beware of denying clinical facts because of physical theories.

To return to our subject-matter, not only do we find ultra-violet rays successful in cases which have resisted those of shorter wave-length, but the converse is true. There are authenticated cases of burns caused by soft X rays, in which a cure has been effected by gamma rays, and even by hard filtered X rays. Such apparently paradoxical effects are possibly associated with the phenomena of "physiological interference" (Leonard Hill). The action of ultra-violet rays, for example, is modified if red light is at the same time caused to fall upon the skin area exposed.

We are now in a position to formulate two principles: (1) The wave-length most suitable for any given type of growth must be found by clinical observation, and cannot be deduced a priori from any physical considerations. (2) If an injury is inflicted by rays of a given wave-length the lesion may in some cases be cured or mitigated by rays of a widely differing wave-length.

II.

We next come to the postulate that if only sufficient rays can be concentrated on to a malignant growth it will be killed; or, to put the belief in a milder form, that the best attainable results are always to be achieved by such a concentration. As regards pelvic growths, techniques of great ingenuity have been elaborated with a view to accomplishing this object. Multiple ports of entry have been long in use, but the rotating tube of Knox undoubtedly enables the idea to be carried out with the maximum of completeness. The theory itself is, however, open to serious criticism. In the first place, it has been proved beyond a doubt, and was admitted at the discussion above referred to, that even rodent ulcer cannot be killed with certainty by any dose of rays short of what is necessary to cause necrosis "en masse"—i.e., unless the rays are used frankly as a caustic. Owing to the impossibility of limiting effects in the depth, such use is, of course, not justifiable. On the other hand, small repeated doses are often quite successful in causing healing.

It will, I think, be generally admitted that a rodent ulcer does best when a fairly wide margin of apparently sound tissue is included in the irradiated area, and when a smart, but not too intense or prolonged, reaction is produced. That a therapeutic up-stirring of the surrounding tissues plays a large part in the cure of *any* cancer is a truth which is slowly gaining the recognition it deserves.

The laboratory observation that a cancerous tumour can be killed in vitro by radiation has limited the progress of clinical radiology. But this is not the fault of the experimenters. For they have also shown that the dose required to kill in vitro is vastly greater than that required to cause disappearances in vivo; also that previous irradiation of a proposed inoculation site reduces very greatly the likelihood of a "take." They have also proved that mild general raying increases resistance to cancer grafts, whereas heavy raying diminishes it.

The search for the cancer dose—the *therapia sterilizans magna*—reminds one of the attitude of many surgeons to the antiseptic dressing of wounds. The search for the ideal antiseptic has gone on for years, and every now and then its discovery is announced. But the results never come up to expectations. The reason is that in most cases antiseptic solutions act as stimulants to the wound rather than as direct killers of germs; and, therefore, are often of most use in solutions so weak as to be quite incapable of any direct lethal action on bacteria. When it was proved that ultra-violet rays could kill germs in vitro, the announcement caused great enthusiasm—an enthusiasm which was damped by the further discovery that this action was prevented by a layer of tissue having a thickness of only a fraction of a millimetre! Yet there is no doubt but that exposure to ultra-violet rays can cause the healing of wounds when the infection is of considerable depth. As Leonard Hill says, the healing is due to an indirect stimulation and is not the result of bactericidal action.

Embryonic cells are specially sensitive to X rays; malignant cells show certain embryonic characteristics; hence malignant cells in the body can be killed by a dose of X rays which will be harmless to normal cells. This imperfect syllogism is the basis of cancer-dose idea, and is analogous to the belief that infected wounds can be healed by an ideal antiseptic which will kill all the bacteria without injuring the body cells. There is, of course, an element of fact in both, but we should beware of being obsessed by one aspect of a truth. That X rays do exert a certain amount of direct action upon neoplastic cells is undoubted; but its amount is peculiarly incalculable, for a tumour should be regarded from a dynamic and not from a static aspect. By this I mean that clinical and microscopic similarity between two tumours at any given moment offers no proof, hardly even a presumption, that they will react in an identical manner to a given dose of radiation. For we know that X ray effect upon growing cells is determined in part upon their degree of activity at the time of application. We cannot gauge this factor when attempting to compare one tumour with another, and thus we can scarcely expect to be able to secure identical results in all patients by a standardised dosage. A malignant tumour is not the inert mass which it looks to the eye, nor are its cells truly represented by the set patterns seen in a "fixed and stained" microscopic preparation. Each cell in the tumour is alive: sometimes resting, sometimes plunging into an orgy of reproductive activity. Let us contemplate this picture with due humility, and beware of attempting prematurely to apply simple mathematical formulæ to complex and imperfectly understood biological processes.

It may be argued that although we can never hope to know beforehand the minimum dose for each tumour, yet a dosage can be administered which will always be the maximum ever required. But clinical experience has now shown that no dosage which it is practicable to administer can ensure that all cancer cells are killed.

This being the case, we have to think very carefully about the surrounding tissues. Cross-fire cannot be limited strictly to the tumour. We do not know its exact size and shape; and it is in the nature of things that the various beams must pass on, still powerful, into the tissues on that aspect of the tumour which is, for the time being, remote from the tube. In other words, it is impossible to concentrate upon the tumour—or, at any rate, upon its periphery, which is the part that matters most—a dose less than that which is received by the parts immediately surrounding it. On these much depends. Hence, for the crude idea of a purely destructive "cancer dose" should be substituted the following principle: *The amount of radiation which is concentrated upon a tumour should not exceed the maximum consistent with the production of a healthy reaction in the surrounding tissues.*

Assuming that, in a particular case, a concentrated dosage has been decided on, is the concentration in space to be paralleled by a similar concentration in time? In other words, is the maximum permissible dose (as clinically determined in accordance with the principle just laid down) to be delivered in one day or spread over several consecutive days? The former method is chiefly associated with the Erlangen school. It is admittedly hard on the patient, may in some cases be fatal; and, whatever the ultimate benefit, causes the appearance of a negative phase, during which the patient shows increased susceptibility to metastatic invasion. What are the arguments used by those in favour of the single dose?

1. They say that the dose required to cause sterilisation in the female has to be very considerably increased if the exposure is made over a period of some days.

This argument is beside the point, for two reasons. In the first place, the effect of X rays upon the reproductive cells is directly destructive. The action of the surrounding tissues does not come in at all. In the nature of the case it cannot, as the reproductive cells are normal to the body. But the cure of cancer by radiation is a subtle mingling of inhibition with stimulation. As we have seen, it is not possible to kill cancer cells by a mathematically calculated dosage, and there is no true analogy between X ray action upon the ovarian cells and upon those of a malignant tumour. In the second place, the mere fact that the dose required to produce a given effect is greater, in sum, when spread over a few days, has no bearing upon the merits of the case. *If the same effect can be produced in one of two ways, that which upsets the patient the least is obviously to be preferred.*

2. There is the argument that, with any division of the dose, there is a risk of actually stimulating the growth. To controvert this is, perhaps, already akin to flogging a dead horse; yet the idea still crops up

occasionally in unexpected quarters. The belief is based on theory alone—for the amount of so-called clinical evidence is so small that, were an equal amount brought forward to prove some benefit, it would be justly dismissed as coming well within the limits of coincidence.

That apparent stimulation of a growth may occur after too intense or too long-continued radiation is true; but this is due to a breakdown of resistance, and is not a true stimulation. We find, in point of fact, that in the two malignant conditions most easily observed—namely, rodent ulcer and cancer of the breast—very small doses cause improvement or even apparent cure. If small quantities of radiation are really dangerous, then the upholders of the stimulation theory have proved too much; for no cases other than those in which the exact size, shape, and position of the growth are known should ever be treated. Otherwise, how shall we know what quantity of rays may reach some outlying spur or metastasis, exciting it to fatal activity? Thus, we see that this particular bogey carried to its logical conclusion ends in a reductio ad absurdum.

III.

The method of concentrated cross-fire is applicable only in the case of tumours of moderate size, the position of which is believed to be known; and when it is assumed that there are no metastases. About the only instance in which these conditions are reasonably fulfilled is an early carcinoma of the uterus, more particularly of the cervix. Of such a nature are the cases on which the Erlangen claims to success are chiefly based; but in those which come into the hands of British radiologists the conditions are far otherwise. In the inoperable case, and in the post-operative recurrence, the disease is no longer limited in extent; consequently, only a wide distribution of radiation can be of avail. Not only so, but surgeons of the school of Mr. Sampson Handley are of opinion that *all* radiation treatment should be as widespread as possible, made to include the microscopically invisible lymphatic invasion, which they say spreads centrifugally from the primary tumour. Whether or not radiation treatment should *always* be widely distributed I do not feel competent to say; but it is, at least, certain that in 90 per cent. of the cases we see in England it is the only method by which we can hope to deal effectively with the disease.

This being admitted, we have to consider very carefully the question of *general effects*. A given exposure below the diaphragm causes more disturbance than the same dosage above; various ductless glands have also to be considered; but, other things being equal, the constitutional upset is proportional to the skin area exposed. This is a matter of clinical experience, and is to be correlated, at least in some degree, with the volume of blood which is irradiated.

In the case of widespread disease, it is impossible to dose the whole area with an intensity which might be safe enough if given over a more limited space. It may be desirable to include a large part of the abdomen, both from the back and from the front; and to give the unit skin dose of the Erlangen school in a single day upon such an area would in all likelihood be fatal to the patient. The area must be contracted, or the skin dose must be reduced, or the time must be greatly extended. From these alternatives there is no escape.

As a corollary to the maxim that concentrated dosage, if given, should not exceed that which is capable of producing healthy reaction in the tissues round a malignant growth, we need to add that *radiation treatment, given by whatsoever method, must be attuned to the estimated power of constitutional response in the individual patient.* A certain amount of disturbance, local or general, is not, of course, an indication of over-dosage, any more than is that which follows successful treatment by a vaccine. But just as the skilful vaccine-therapist seeks to avoid violent reactions in general, and, in the case of feeble patients, errs on the side of caution, so the wise radiologist will be chary of reactions in his stronger patients, and avoid them altogether in those of low vitality. That there is a close analogy between the action of X rays in microbial diseases and that of vaccines is undeniable. They seem to help the body to produce suitable antitoxins, irrespective of the particular organisms. The present tendency of bacteriologists to modify their views as to the specificity of vaccines makes this the more probable. Medicine is an organic whole, and it will pay the radiologist, although he cannot hope to master details, to follow the general trend of modern clinical bacteriology. The problems of immunity, the production of negative and positive phases, and, lastly, of anaphylaxis, can be neglected only at grave peril to the progress of radio-therapeutics.

This is perhaps a suitable place to refer to the effects of potassium in various forms. From time to time cases are published which seem to indicate that this element has some beneficial effect on malignant growths. This, at least, is certain: that in the case of pathological fibrous tissue, such as keloid, Dupuytren's contraction, &c., the exhibition of potassium may produce precisely the same effect as X ray exposures. Of this I can speak from personal observation. We find X rays producing in various cases results which may be obtained in other ways—e.g., by arsenic or thyroid in psoriasis; by vaccines in acne or tubercle; by potassium in keloid, and possibly in cancer. This chaos is, we may be sure, apparent only, but its existence is sufficient to show that the problems of radio-therapeutics cannot be divorced from those of medicine in general.

IV.

So far we have been dealing for the most part with what may be classed under the general head of intensive therapy—i.e., treatment extending over not more than a few days, followed by an interval of at least several weeks. Such treatment is inevitably accompanied by at least some disturbance—which may, however, be very slight in people whose general health is still fair. But it is quite possible, and, indeed, was formerly the custom, to treat malignant cases without producing any apparent reaction. The small dose, repeated two or three times a week for perhaps two months, will cause shrinkage or disappearance of some cancerous tumours, notably of the breast. The general health improves pari passu, and this benefit is noticeable very early, sometimes after the first week.[1]

I have already referred to the experiments of Russ in this country, and of Murphy and Bainbridge in America, to the effect that a considerable degree of immunity to cancer grafts can be produced in rodents by suitable irradiation, whereas an excess lowers or abolishes resistance. The sense of well-being which accompanies suitable divided dosage in human beings, combined with the fact that nodules outside the area irradiated sometimes disappear, give ground for the belief that a similar phenomenon occurs in man. At any rate, the clinical results of this method are such that we are not justified in resorting to anything more drastic in the case of the old feeble, or when attempting to render an inoperable case operable. This statement requires some modification, in that, should mild measures fail, one ought to try others, even at some immediate risk. For prophylaxis the divided dosage should always be used.

V.

Reference must now be made to what may be termed the constitutional side of the therapeutic problem. The broad fact is that patients in good general health respond the best, whereas those in a cachectic state sometimes fail to show even temporary benefit. Whatever is the nature of cancer, whether it is a germ disease or a biological "throw-back," we know the body unaided resists its progress—often by rays of a given wave-length the lesion may in some cases be cured or mitigated by rays of a widely differing wave-length.

---

[1] When I speak of small doses I mean doses of the order of 2 m.a., 30 cm. antikathode—skin; 3 mm. aluminium filter; 140–160 kilo-volt; time, 10 min. The largest possible diaphragm is used, so a skin area at least 1 ft. in diameter is exposed.

II.

We next come to the postulate that if only sufficient rays can be concentrated on to a malignant growth it will be killed; or, to put the belief in a milder form, that the best attainable results are always to be achieved by such a concentration. As regards pelvic growths, techniques of great ingenuity have been elaborated with a view to accomplishing this object. Multiple ports of entry have been long in use, but the rotating tube of Knox undoubtedly enables the idea to be carried out with the maximum of completeness. The theory itself is, however, open to serious criticism. In the first place, it has been proved beyond a doubt, and was admitted at the discussion above referred to, that even rodent ulcer cannot be killed with certainty by any dose of rays short of what is necessary to cause necrosis "en masse"—i.e., unless the rays are used frankly as a caustic. Owing to the impossibility of limiting effects in the depth, such use is, of course, not justifiable. On the other hand, small repeated doses are often quite successful in causing healing.

It will, I think, be generally admitted that a rodent ulcer does best when a fairly wide margin of apparently sound tissue is included in the irradiated area, and when a smart, but not too intense or prolonged, reaction is produced. That a therapeutic up-stirring of the surrounding tissues plays a large part in the cure of *any* cancer is a truth which is slowly gaining the recognition it deserves.

The laboratory observation that a cancerous tumour can be killed in vitro by radiation has limited the progress of clinical radiology. But this is not the fault of the experimenters. For they have also shown that the dose required to kill in vitro is vastly greater than that required to cause disappearances in vivo; also that previous irradiation of a proposed inoculation site reduces very greatly the likelihood of a "take." They have also proved that mild general raying increases resistance to cancer grafts, whereas heavy raying diminishes it.

The search for the cancer dose—the *therapia sterilizans magna*—reminds one of the attitude of many surgeons to the antiseptic dressing of wounds. The search for the ideal antiseptic has gone on for years, and every now and then its discovery is announced. But the results never come up to expectations. The reason is that in most cases antiseptic solutions act as stimulants to the wound rather than as direct killers of germs; and, therefore, are often of most use in solutions so weak as to be quite incapable of any direct lethal action on bacteria. When it was proved that ultra-violet rays could kill germs in vitro, the announcement caused great enthusiasm—an enthusiasm which was damped by the further discovery that this action was prevented by a layer of tissue having a thickness of only a fraction of a millimetre! Yet there is no doubt but that exposure to ultra-violet rays can cause the healing of wounds when the infection is of considerable depth. As Leonard Hill says, the healing is due to an indirect stimulation and is not the result of bactericidal action.

Embryonic cells are specially sensitive to X rays; malignant cells show certain embryonic characteristics; hence malignant cells in the body can be killed by a dose of X rays which will be harmless to normal cells. This imperfect syllogism is the basis of cancer-dose idea, and is analogous to the belief that infected wounds can be healed by an ideal antiseptic which will kill all the bacteria without injuring the body cells. There is, of course, an element of fact in both, but we should beware of being obsessed by one aspect of a truth. That X rays do exert a certain amount of direct action upon neoplastic cells is undoubted; but its amount is peculiarly incalculable, for a tumour should be regarded from a dynamic and not from a static aspect. By this I mean that clinical and microscopic similarity between two tumours at any given moment offers no proof, hardly even a presumption, that they will react in an identical manner to a given dose of radiation. For we know that X ray effect upon growing cells is determined in part upon their degree of activity at the time of application. We cannot gauge this factor when attempting to compare one tumour with another, and thus we can scarcely expect to be able to secure identical results in all patients by a standardised dosage. A malignant tumour is not the inert mass which it looks to the eye, nor are its cells truly represented by the set patterns seen in a "fixed and stained" microscopic preparation. Each cell in the tumour is alive: sometimes resting, sometimes plunging into an orgy of reproductive activity. Let us contemplate this picture with due humility, and beware of attempting prematurely to apply simple mathematical formulæ to complex and imperfectly understood biological processes.

It may be argued that although we can never hope to know beforehand the minimum dose for each tumour, yet a dosage can be administered which will always be the maximum ever required. But clinical experience has now shown that no dosage which it is practicable to administer can ensure that all cancer cells are killed.

This being the case, we have to think very carefully about the surrounding tissues. Cross-fire cannot be limited strictly to the tumour. We do not know its exact size and shape; and it is in the nature of things that the various beams must pass on, still powerful, into the tissues on that aspect of the tumour which is, for the time being, remote from the tube. In other words, it is impossible to concentrate upon the tumour—or, at any rate, upon its periphery, which is the part that matters most—a dose less than that which is received by the parts immediately surrounding it. On these much depends. Hence, for the crude idea of a purely destructive "cancer dose" should be substituted the following principle: *The amount of radiation which is concentrated upon a tumour should not exceed the maximum consistent with the production of a healthy reaction in the surrounding tissues.*

Assuming that, in a particular case, a concentrated dosage has been decided on, is the concentration in space to be paralleled by a similar concentration in time? In other words, is the maximum permissible dose (as clinically determined in accordance with the principle just laid down) to be delivered in one day or spread over several consecutive days? The former method is chiefly associated with the Erlangen school. It is admittedly hard on the patient, may in some cases be fatal; and, whatever the ultimate benefit, causes the appearance of a negative phase, during which the patient shows increased susceptibility to metastatic invasion. What are the arguments used by those in favour of the single dose?

1. They say that the dose required to cause sterilisation in the female has to be very considerably increased if the exposure is made over a period of some days.

This argument is beside the point, for two reasons. In the first place, the effect of X rays upon the reproductive cells is directly destructive. The action of the surrounding tissues does not come in at all. In the nature of the case it cannot, as the reproductive cells are normal to the body. But the cure of cancer by radiation is a subtle mingling of inhibition with stimulation. As we have seen, it is not possible to kill cancer cells by a mathematically calculated dosage, and there is no true analogy between X ray action upon the ovarian cells and upon those of a malignant tumour. In the second place, the mere fact that the dose required to produce a given effect is greater, in sum, when spread over a few days, has no bearing upon the merits of the case. *If the same effect can be produced in one of two ways, that which upsets the patient the least is obviously to be preferred.*

2. There is the argument that, with any division of the dose, there is a risk of actually stimulating the growth. To controvert this is, perhaps, already akin to flogging a dead horse; yet the idea still crops up

occasionally in unexpected quarters. The belief is based on theory alone—for the amount of so-called clinical evidence is so small that, were an equal amount brought forward to prove some benefit, it would be justly dismissed as coming well within the limits of coincidence.

That apparent stimulation of a growth may occur after too intense or too long-continued radiation is true; but this is due to a breakdown of resistance, and is not a true stimulation We find, in point of fact, that in the two malignant conditions most easily observed—namely, rodent ulcer and cancer of the breast—very small doses cause improvement or even apparent cure. If small quantities of radiation are really dangerous, then the upholders of the stimulation theory have proved too much; for no cases other than those in which the exact size, shape, and position of the growth are known should ever be treated. Otherwise, how shall we know what quantity of rays may reach some outlying spur or metastasis, exciting it to fatal activity? Thus, we see that this particular bogey carried to its logical conclusion ends in a reductio ad absurdum.

III.

The method of concentrated cross-fire is applicable only in the case of tumours of moderate size, the position of which is believed to be known; and when it is assumed that there are no metastases. About the only instance in which these conditions are reasonably fulfilled is an early carcinoma of the uterus, more particularly of the cervix. Of such a nature are the cases on which the Erlangen claims to success are chiefly based; but in those which come into the hands of British radiologists the conditions are far otherwise. In the inoperable case, and in the post-operative recurrence, the disease is no longer limited in extent; consequently, only a wide distribution of radiation can be of avail. Not only so, but surgeons of the school of Mr. Sampson Handley are of opinion that *all* radiation treatment should be as widespread as possible, made to include the microscopically invisible lymphatic invasion, which they say spreads centrifugally from the primary tumour. Whether or not radiation treatment should *always* be widely distributed I do not feel competent to say: but it is, at least, certain that in 90 per cent. of the cases we see in England it is the only method by which we can hope to deal effectively with the disease.

This being admitted, we have to consider very carefully the question of *general effects*. A given exposure below the diaphragm causes more disturbance than the same dosage above; various ductless glands have also to be considered; but, other things being equal, the constitutional upset is proportional to the skin area exposed. This is a matter of clinical experience, and is to be correlated, at least in some degree, with the volume of blood which is irradiated.

In the case of widespread disease, it is impossible to dose the whole area with an intensity which might be safe enough if given over a more limited space. It may be desirable to include a large part of the abdomen, both from the back and from the front; and to give the unit skin dose of the Erlangen school in a single day upon such an area would in all likelihood be fatal to the patient. The area must be contracted, or the skin dose must be reduced, or the time must be greatly extended. From these alternatives there is no escape.

As a corollary to the maxim that concentrated dosage, if given, should not exceed that which is capable of producing healthy reaction in the tissues round a malignant growth, we need to add that *radiation treatment, given by whatsoever method, must be attuned to the estimated power of constitutional response in the individual patient.* A certain amount of disturbance, local or general, is not, of course, an indication of over-dosage, any more than is that which follows successful treatment by a vaccine. But just as the skilful vaccine-therapist seeks to avoid violent reactions in general, and, in the case of feeble patients, errs on the side of caution, so the wise radiologist will be chary of reactions in his stronger patients, and avoid them altogether in those of low vitality. That there is a close analogy between the action of X rays in microbial diseases and that of vaccines is undeniable. They seem to help the body to produce suitable antitoxins, irrespective of the particular organisms. The present tendency of bacteriologists to modify their views as to the specificity of vaccines makes this the more probable. Medicine is an organic whole, and it will pay the radiologist, although he cannot hope to master details, to follow the general trend of modern clinical bacteriology. The problems of immunity, the production of negative and positive phases, and, lastly, of anaphylaxis, can be neglected only at grave peril to the progress of radio-therapeutics.

This is perhaps a suitable place to refer to the effects of potassium in various forms. From time to time cases are published which seem to indicate that this element has some beneficial effect on malignant growths. This, at least, is certain: that in the case of pathological fibrous tissue, such as keloid, Dupuytren's contraction, &c., the exhibition of potassium may produce precisely the same effect as X ray exposures. Of this I can speak from personal *observation. We find X rays producing in various* cases results which may be obtained in other ways —e.g., by arsenic or thyroid in psoriasis; by vaccines in acne or tubercle; by potassium in keloid, and possibly in cancer. This chaos is, we may be sure, apparent only, but its existence is sufficient to show that the problems of radio-therapeutics cannot be divorced from those of medicine in general.

IV.

So far we have been dealing for the most part with what may be classed under the general head of intensive therapy—i.e., treatment extending over not more than a few days, followed by an interval of at least several weeks. Such treatment is inevitably accompanied by at least some disturbance—which may, however, be very slight in people whose general health is still fair. But it is quite possible, and, indeed, was formerly the custom, to treat malignant cases without producing any apparent reaction. The small dose, repeated two or three times a week for perhaps two months, will cause shrinkage or disappearance of some cancerous tumours, notably of the breast. The general health improves pari passu, and this benefit is noticeable very early, sometimes after the first week.[1]

I have already referred to the experiments of Russ in this country, and of Murphy and Bainbridge in America, to the effect that a considerable degree of immunity to cancer grafts can be produced in rodents by suitable irradiation, whereas an excess lowers or abolishes resistance. The sense of well-being which accompanies suitable divided dosage in human beings, combined with the fact that nodules outside the area irradiated sometimes disappear, give ground for the belief that a similar phenomenon occurs in man. At any rate, the clinical results of this method are such that we are not justified in resorting to anything more drastic in the case of the old feeble, or when attempting to render an inoperable case operable. This statement requires some modification, in that, should mild measures fail, one ought to try others, even at some immediate risk. For prophylaxis the divided dosage should always be used.

V.

Reference must now be made to what may be termed the constitutional side of the therapeutic problem. The broad fact is that patients in good general health respond the best, whereas those in a cachectic state sometimes fail to show even temporary benefit. Whatever is the nature of cancer, whether it is a germ disease or a biological "throw-back," we know the body unaided resists its progress—often for years, occasionally with permanent success. In cases which are rapidly going to the bad—in which, apparently, resistance is almost exhausted—we may sometimes by suitable X ray treatment produce a miraculous restoration to apparent health, which is usually only of a few months', but may be of some years' duration. Sooner or later, there is only too likely to occur a sudden and complete "going to pieces"—death occurring sometimes as the result of recurrence at the original site, but more often from widespread and rapidly growing metastases. The power of resistance seems to come to an abrupt end. A somewhat similar phenomenon sometimes occurs in tubercle. When this rapid collapse sets in, further X rays are, as a rule, useless; nor does experience so far lead us to hope that heavy dosage in the interval will avert such disasters.

---

[1] When I speak of small doses I mean doses of the order of 2 m.a., 30 cm. antikathode—skin; 3 mm. aluminium filter; 140–160 kilo-volt; time, 10 min. The largest possible diaphragm is used, so a skin area at least 1 ft. in diameter is exposed.

It has been suggested that those malignant cells which are not killed in the first attack may acquire immunity to further dosage, and transmit this to their descendants. The question of inheritance of acquired immunity is a somewhat vexed one. It is perhaps simpler to assume that certain cells by reason of variation, or even of mutation, have inherently a higher resisting power; that these alone survive, and their descendants inherit the favourable character. It should also be noted that the immunity may be against the means of attack possessed by the body—which mechanism is stirred into activity by X ray treatment—rather than against any direct effects of the radiation. This is not merely a "distinction without a difference"—it has an obvious bearing on the lines which research should follow.

It has seemed desirable to mention this view of the tumour becoming immune to X rays; but, to the present writer, it appears more probable that death results from a failure of resisting power, local and general. If the tumour mass is reproduced from immune cells, one would expect trouble to begin very soon after the treatment, and to progress steadily—unless one assumes that the malignant cells lie paralysed for a long period, and then leap into furious activity. Even this somewhat far-fetched hypothesis will not suffice, unless we also assume that all the metastatic deposits are started after the latent period—an assumption very hard to reconcile with clinical facts.

Let us consider a typical case illustrating the measure of success, followed by final failure, which can be paralleled from the case-books of any experienced radiologist. A patient is seen, let us say, in January fast dying of pelvic cancer. She has a few days intensive treatment, and in two months she has put on 20 lb. in weight and returned to her ordinary occupation. Examination at the end of April reveals only slight traces of palpable disease.

It would appear that the patient is in a much more favourable condition for X ray treatment than when she first came. Yet, whatever is done in that way, she may be dead before the end of the year. Occasionally it is not so, and a second restoration may occur, or an interval treatment may appear to postpone the final collapse. Generally speaking, however, a repetition of the treatment gives disappointing results, and may even appear to do harm. In the latter case X ray anaphylaxis, which appears really to exist, may explain the failure—but this cannot account for all cases. Our patient, so desperately ill in January, yet had then some power of response which, unrecognisably better in April, she had nevertheless ceased to possess.

The failure of our efforts to take advantage of the "period of grace" in such cases to consolidate the ground won, and to use it as a basis for further advance is, perhaps, the greatest disappointment of modern medicine. Yet our experience with rodent ulcer, which extends over a quarter of a century, should have warned us of what to expect. Almost all rodent ulcers can be made to disappear once by X rays; sometimes twice. But such as recur once recur again, and are rarely amenable to a third course of treatment. They become "immune" or—as I prefer to put it—the surrounding tissues lose the power of response. It is my practice never to treat a recurring rodent ulcer again with X rays alone. But if the visible growth be destroyed by the curette, X rays will induce rapid healing of the wound. The mechanical stimulus of scraping, the flushing with fresh blood, &c., appears to restore the capacity of the tissues to react. The same result may sometimes be accomplished by first ionising with zinc or copper.

Recent work on vaccine therapy tends to show that in many cases injections act best if made within the tissues which are the actual seat of disease. For example, in the case of pyorrhœa, subcutaneous injections produce some benefit, but if the gum is chosen as the site, the effect is much more pronounced. It is assumed that the invaded tissue is capable of a special resistance over and above that offered by the body in general. Now, it would appear that the resistance to cancerous growth is also local and general. A rodent ulcer has no tendency to metastasis, and therefore, in treating it, we are chiefly concerned with local resistance. Breast and uterine cancers call for an opposition both local and general.

In the case of deep-seated tumours, attempts at local "resensitisation" must at present be empirical. They are limited to the passing of diathermic currents or heavy continuous currents through the site of the growth, and the injection of colloidal metals in such a manner that they reach the general circulation. Blair Bell's experiments with lead should be kept in view in this connexion.

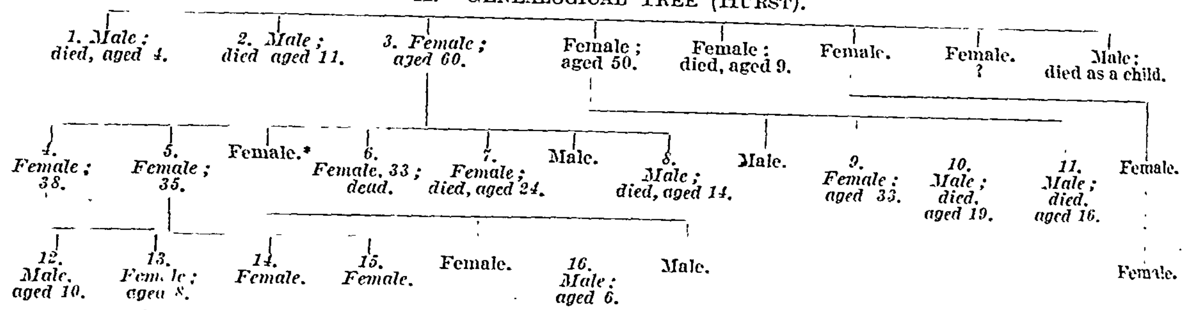
In the matter of raising the general resistance, we are on somewhat firmer ground. There are certain experimental and clinical hints on which we may act. Rats fed on a vitamin-excess diet are very resistant to cancer grafts; let us give our patients a suitable diet. Again, patients whose blood is normal in every respect respond well to X rays. Sunlight increases the red cells and the hæmoglobin index. See that patients have it—natural, if possible; it not, then synthetic. The "open-air cure" is as important in cancer as in tubercle, but the exposure of delicate patients to the outdoor conditions of an English winter is not to be recommended, unless artificial sunlight is supplied when there is none from above.

Closely associated with the question of general resistance is the mental attitude of patients. There can be little doubt but that some of them literally worry themselves into their graves. In this connexion it is interesting to recall the history of tuberculosis of the lungs. Twenty years ago there was almost the same reluctance to tell a patient he was suffering from "consumption", as now to inform him that he has cancer. The public dread of the disease is now much less, and it is possible to deal with most lung patients as rational beings. From a long experience, I cannot help feeling that well-meant attempts to conceal from a patient that he has cancer are often only partially successful. With men, it is, as a rule, scarcely worth while to make the attempt; and it becomes increasingly difficult to conceal the truth from women, while at the same time taking those measures which offer the best scope of recovery. A brutal announcement of "cancer" at the first consultation often does irreparable harm; but the patient can be accustomed gradually to the idea without the word being actually mentioned. Only thus can we secure the full coöperation of the patient, who cannot otherwise understand why she should be medically watched after her "lump" has disappeared. Attempts at such watching and prophylaxis, without full explanation, often lead to suspicion and even resentment. Some of my most cheerful patients are women who are quite aware of what is the matter with them, and upon whom no greater deception has been practised than the representation to them that their individual cases are an especially favourable type of a grave disease. I am, in short, in favour of greater frankness; while quite recognising that there are people, who, if convinced that they had cancer, would forthwith turn their faces to the wall and die.

drinking claret. There is no history of nephritis in the other five members of that generation. The children of Case 3 all seem to have suffered from the same condition as the mother—intermittent attacks of hæmaturia which could be brought on by eating certain substances, usually black currants. The attacks in these members of the family seem to have been more of the nature of a pure hæmaturia than a parenchymatous nephritis. Though they were associated with malaise and some fever, tube casts, other than blood casts, did not appear in the urine; there is no history of œdema or of cardio-vascular disturbance. Case 8 was more severe than the others, and pericarditis, presumed to be of a nephritic origin, was a terminal complication.

Leonard G. Guthrie made a study of this part of the family[4] and describes the condition as "idiopathic or congenital hereditary and family hæmaturia" in the following terms:—That it is: (1) Hereditary—familial and congenital; (2) persistent for many years, but may vary in extent; (3) liable to paroxysmal exacerbations with influenzal-like symptoms; (4) not marked by œdema, ascites, or cardio-vascular disturbance; (5) not due to uric acid or oxalates; (6) not accompanied by urine of low specific gravity (1015–1020). From these facts Guthrie omits the word "nephritis" and favours "hæmaturia" in describing the condition.

A.—GENEALOGICAL TREE (HURST).



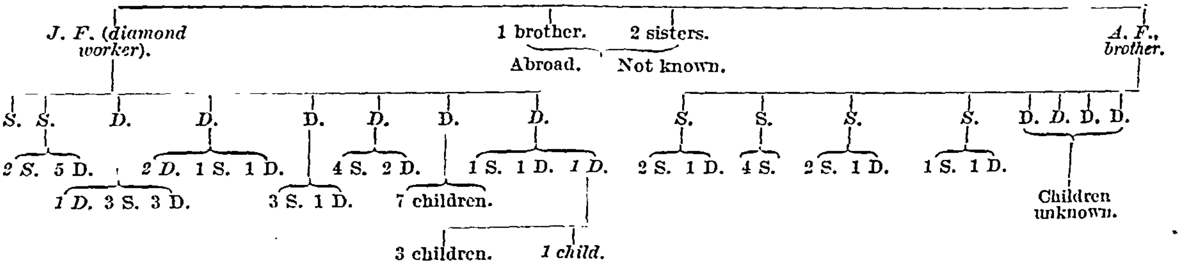
Cases suffering from nephritis are italicised. * Has had attacks of epistaxis and hæmatemesis.

Second Generation.—The second part of the second generation, described by Hurst, consisting of three males and one female, were descended from a mother who had not suffered from any renal derangement, but two of the males and the female member were affected with what appears to be a definite nephritis and very little hæmaturia. The one female (Case 9) is well, but has had albuminuria since 3 weeks of age. Two brothers, however, showed severe symptoms. One (Case 10) was found to have albumin in the urine at the age of 14, after which the albuminuria persisted, together with attacks of hæmaturia after exertion, to terminate in death from uræmia at the age of 19, after an attack of influenza. The other brother (Case 11) was found to suffer from albuminuria when 2 years of age, persisting till his death at the age of 16 years. When he was 12 years old there was no œdema, but the blood pressure measured 143 mm. of mercury. The urine at this time was albuminous, contained numerous blood cells, and granular and hyaline casts. When seen two years later he was pale and anæmic, had had several attacks of sickness, the blood was 137 mm. Hg and the heart considerably hypertrophied. His urine contained, in addition to the albumin, casts of a coarsely granular and fatty-epithelial nature. The specific gravity was 1010. Shortly after this he became uræmic, with anuria, and showed some puffiness of the face. He recovered from this, but died in his sleep shortly after. The symptoms of this part of the family show definite nephritis, mainly of the interstitial type. Œdema and cardio-vascular disturbance are marked features, while the specific gravity of the urine was less than 1015. Guthrie's description—family hæmaturia—given to Cases 3, 6, 7, and 8 is, therefore, not applicable in Cases 9, 10, and 11.

Hurst has made further investigations upon this interesting family, and has been good enough to permit us to give recent data which supplement what he has already published. The new facts concerning this branch of the family are that a daughter of the fifth member of the first generation, a mother free from kidney disease, is herself free and has a daughter in the third generation also entirely free—thus, this branch of the family seems to have escaped the trouble affecting the rest of the family.

Third Generation.—In his communication Hurst mentioned only Case 12 of the third generation, but children have since been born, four of whom are affected with kidney disease. Case 12, a male child of Case 4, a female who is "subject to attacks of hæmaturia," but apparently not of a serious nature. The child, at present 10 years of age, had an attack of hæmaturia in infancy, and later a sore-throat and temperature of 102° F. After this he suffered for six weeks from albuminuria, together with hyaline, epithelial, and granular casts. This condition has cleared up to some extent, but has left an apparently high blood pressure. This child has a sister of 8 years (Case 13), who is affected, but of whom there are no details. Case 5, a female who does not suffer severely, has two female children who are affected (Cases 14 and 15). The third daughter of Case 3, sister of Cases 4, 5, 6, 7, and 8, who suffers from epistaxis and hæmatemesis but not from hæmaturia, has a daughter and two sons, one son being affected—in this case the condition has missed a generation.

B.—GENEALOGICAL TREE (PEL).



Those suffering from nephritis are italicised. S. = son. D. = daughter.

In naming the condition, Hurst has employed the terms "hereditary, familial, congenital, hæmorrhagic nephritis." The condition fulfils all these descriptions. After a broader survey of the family than Guthrie's, Hurst prefers the term "nephritis," as being more accurate than "hæmaturia." Throughout the family the males seem to be affected very much more than the females, all the affected male members having succumbed except the two children of the third generation. The females, on the other hand, seem to be affected only to a slight extent, slight albuminuria, together with hæmaturia in the majority of cases, and then only under certain conditions. It would be interesting to note later if the condition was carried down by the male members as it has been by the females.

A family has been very fully investigated by Pel.[5] Three generations are given fully and a fourth mentioned—in all there are 19 cases of nephritis. The main familial points in the tree are shown in Tree B—fuller detail may be found in the original article.

The cases appear to have been of a chronic interstitial type, and several are stated to have died in uræmia. Throughout this family, the males and females appear to be affected equally. In the third generation the disease seems to be lessening, though one member has a child in a fourth

The father died of apoplexy at the age of 75, the mother died of apoplexy at the age of 68. An uncle, brother of the mother, died of apoplexy at the age of 60. A sister had acute nephritis with terminal apoplexy at the age of 51, and a brother died of chronic Bright's disease at the age of 46. Our patient had nothing abnormal in her general appearance except dilated turgid capillaries about the end of the nose. She was found to be suffering from chronic interstitial nephritis, marked arterio-sclerosis, and hyperpiesia with cardiac hypertrophy. The systolic blood pressure was 230 mm. Hg. On most days there was a trace of albumin in the urine. The specific gravity varied from 1012–1022. Reaction acid. Oxalate crystals, epithelial and red blood cells were present in the urine on admission. The amount of urine was never more than 50 oz. daily and was usually much less. The blood-urea was not increased.

The renal function tests made were as follows:—9 A.M.: 210 c.cm., 0·8 urea, 22 phenol-sulphon-phthalein (P.S.P.); 10 A.M.: 100 c.cm., 1·7 urea, 17 P.S.P. The Wassermann test was negative.

A family, composed of the father and mother, three sons and two daughters, has also recently come under our observation. Three sons and one daughter were found to be suffering from definite symptoms of renal involvement, and were admitted to hospital under our charge. The other daughter was compelled to give up attendance at school before the statutory leaving age, owing to the state of her heart and general health. There is also in this case evidence of a kidney defect.

We endeavoured to elucidate the relative significance of hereditary and acquired ætiological factors in these cases.

Question of Hereditary Factors.

Nephritis in the Antecedents.—An uncle died in the R.I.E. in 1920, from nephritis, but we have been unable to trace the record. An uncle is at present suffering from chronic nephritis. On examination of the father's urine, on one occasion only, no albumin, cells, or tube casts were present. The mother was apparently healthy.

Syphilis.—We examined the family to ascertain whether syphilis might have been a causal factor in the production of arterio-sclerosis. None of the stigmata of syphilis were present in any member of the family, and in the blood of the three sons the Wassermann test gave negative results. The blood of the daughter who presented symptoms of renal involvement was not submitted to the test. The family seems, however, to be free from all syphilitic taint.

Question of Acquired Factors.

The discovery of nephritis in four young members of one family, more or less about the same time, suggests some common acquired causal factor. It is improbable that each of the cases had a different cause. The facts relative to these matters are given in the records of the individual cases.

Although these cases of nephritis were diagnosed within a few weeks of each other, we are quite unable to say, even approximately, the dates of origin. The symptoms observed were, in fact, interpreted as exacerbations of previously existing kidney disorder, but showing no manifestations of the condition, as no previous history was obtained in any of the four patients studied.

Surroundings at Home and at Work.

The family lives in a house consisting of a room, kitchen, scullery, and lavatory. Living in this are nine persons: Father and mother, three sons (aged 20, 19, and 18), two daughters (aged 14 and 10), two lodgers (men). The house is situated in a street. The water-supply is derived from a distant reservoir and is laid on to all the houses separately in pipes (not a common pipe outside). Food is supplied by local tradesmen, and in no way differs from that supplied to other inhabitants of the street. All the male members of the family are coalminers. Work at the mine is in two shafts, the west and the south. The former contains a foot deep of water, but the temperature is moderate. The latter is dry but extremely hot, causing those working in it to become soaked in perspiration. The work of the boys is that of "drawer," and consists in hauling "hutches" back from the coal face. At the end of the trip in the south working they have to wait and are apt to get chilled after the heat. This south shaft has a bad reputation amongst miners, but on account of the heat they have to work in and not on account of any illness, other than chill, contracted while working there. Food and a bottle of water are carried by the workers. No water is obtainable at the pit for drinking, and tea cannot be made there. Symptoms pointing to renal disorder, such as are complained of by the boys, are evidently uncommon, and have not been noticed by them, or their mother, either at the mine or in the district.

Records of the Cases.

David S., aged 18, coalminer. Was admitted on May 16th, 1922, complaining of swelling of the face and pain in the head. The history was that five days before admission he caught a chill, playing football. It was learned, on further inquiry, that there had been some swelling of the face two months before the onset of the illness for which he was admitted. In infancy he had measles, and during childhood the tonsils were removed. He does not appear to have had any other illnesses. On examination his face was swollen and puffy, but not very œdematous. His complexion was pasty. He had no marked anæmia. Examination of the urinary system showed the presence of albumin, blood, and casts—albumin about 10 g. per litre. The casts were chiefly composed of broken-down epithelium and blood cells. Streptococci were isolated from the urine on three occasions. (No subjective symptoms were complained of.) The non-protein nitrogen of the blood was 42 mg. per 100 c.cm. The urea concentration in the second hour was 1·7 per cent. The P.S.P. excretion was high—95 per cent. being returned in two hours.

Renal efficiency tests, June 28th, 1922:—First hour: 270 c.cm., 1·1 per cent. urea, 60 per cent. P.S.P.; second hour: 113 c.cm., 1·7 per cent. urea, 35 per cent. P.S.P.

The heart was somewhat enlarged, the apex being 4¼ inches from the middle line. Diffuse pulsation was seen in the fourth and fifth intercostal spaces, and the movement was heaving in character. The heart sounds were closed. The radial artery was definitely palpable, and the systolic blood pressure (taken on May 21st) was 172 mm. Hg. Blood culture yielded a growth of streptococci on one occasion. Ten teeth were present in each jaw. These were carious and in a septic condition. The breath was rather foul. There was no congestion of the fauces. A mixed growth of organisms was obtained from the teeth and tonsillar region, with streptococci preponderating. The Wassermann reaction was negative.

The patient was first put on a salt-free diet, and later on light diet. Daily hot-air baths were given. The further course was that the œdema gradually disappeared; the albuminuria was somewhat obstinate, ranging during the first eight days from 6 to 15 g. per litre, dropping gradually to 1 g. per litre, and remaining at this. Hæmaturia occurred on ten occasions, and ceased shortly before his discharge from hospital in the early part of August. Blood, epithelial cells, and granular casts were noted once. When we saw him again by request, four months after his discharge from hospital (seven months after admission), a mere opalescence appeared on heating the urine, and streptococci were obtained in cultures. The S.B.P. was 126, and the apex beat of the heart was 3½ inches from the mid-line. He had been at work since his discharge and had felt entirely well.

John S., aged 20, coalminer, was admitted to hospital on June 6th, 1922. Complaint: Swelling of face; pain in back; headache, which had been present four days. He had worked in both the wet and the hot shafts—in the latter he worked stripped to the waist, and he had only worked nine days there when he was taken ill. He consulted his doctor, who sent him to hospital. The only previous illness of any importance was osteomyelitis ten years previously, when part of the right tibia was removed. He had not required medical attendance in recent years. He had not had scarlet fever. There was no history of previous attacks of nephritis. On examination, his face was puffy around the eyes but not very œdematous.

Examination of the urinary system: No subjective symptoms were complained of. The urine was passed in good quantities (1136–1845 c.cm. per diem). Traces of blood were present, and albumin to the extent of 4 g. per litre. Granular and hyaline casts were present, but no organisms, pus, or epithelial cells were found in a stained film. No growth was obtained on culture. The non-protein nitrogen of the blood was 36 mg. per 100 c.cm. The urea concentration in the second hour was 2·3 per cent.

The P.S.P. excretion was not good, 50 per cent. being returned in two hours. First hour: 183 c.cm., 1·4 per cent. urea, 35 per cent. P.S.P.: second hour: 106 c.cm., 2·3 per cent. urea, 15 per cent. P.S.P. A blood count showed some leucocytosis.

The apex of the heart was 3¾ in. from the mid-line. There was a slight systolic murmur at the mitral area, but no accentuation of the second sound. No subjective symptoms were complained of. The wall of the radial artery was definitely palpable. The arterial wave was slow in upstroke and downstroke and well sustained, the vessel was not easily compressed. The systolic blood pressure was 148 mg. Hg. No growth was obtained from blood cultures on two occasions. The fundus oculi showed no changes. Six teeth were in bad condition, but there was no pyorrhœa alveolaris. The tongue was slightly furred: the fauces healthy. The Wassermann reaction was negative.

The patient responded to treatment more quickly than in the last case, the blood disappearing from the urine and the albumin diminishing to a trace. Four months after leaving hospital the urine was completely free of albumin, the S.B.P. was 142 mm. Hg (the arteries were very definitely palpable), œdema was absent, and no subjective symptoms were complained of. Stained films of the urine were bacteriologically negative.

Joseph S., aged 19, coalminer, was admitted to hospital on June 26th, 1922, as we wished to examine as many members of the family as were willing to present themselves. He had been unemployed for a fortnight previous to admission, but had felt fit and well. Before this he had worked in both shafts. Complaint: Swelling of the face, commencing one week before admission, but of no other symptoms. On examination, patient showed some puffiness under the eyes, but he did not feel ill in any way. The swelling had been present for one week. He could remember no illness, even during childhood. Examination of the urinary system showed slight frequency of micturition—he had to rise once during the night. The quantity per diem was 994–1278 c.cm. The urine itself showed a trace of blood, and albumin to the extent of 1 to 3 g. per litre. Hyaline casts, red blood corpuscles, and epithelial cells were found in the deposit. Cultural examination was negative.

On July 10th the non-protein nitrogen of the blood was 38 mg. per 100 c.cm. Urea concentration in the second hour was 2·6 per cent. P.S.P. elimination good, at 80 per cent. in two hours. First hour: 73 c.cm., 2·3 per cent. urea, 45 per cent. P.S.P.; second hour: 82 c.cm., 2·6 per cent. urea, 35 per cent. P.S.P.

Examination of the circulatory system revealed no subjective symptoms. The heart was somewhat enlarged, the apex being 4¼ in. from the mid-line—it was forcible in character, though not increased in extent. The wall of the radial artery was definitely palpable. Systolic blood pressure was 172 mm. Hg. No growth was obtained from blood cultures. Teeth were in fair condition and gums healthy. Tonsils not enlarged. Wassermann reaction of the blood negative. In cultures from teeth and tonsils streptococcal colonies were numerous.

Patient responded well to treatment, and showed a decrease of blood pressure to 143 mm. Hg and the albumin and blood in the urine diminished to a trace. A few well-formed granular casts were present on one occasion. On examination four months after leaving hospital there was only a faint trace of albumin in the urine, the heart had diminished in size, the apex being 3¼ in. from the mid-line, the first sound was dull and the second slightly accentuated, the S.B.P. was 139, and the arterial wall palpable.

Alice S., aged 10. It was heard that this girl was suffering from some urinary trouble, and she was sent for and admitted to hospital. It appeared that six months previously she had some pain in the right iliac fossa, and she was then seen in the Royal Hospital for Sick Children. There she was X rayed and told there was "something growing round the kidney." She had had measles. On admission, there was no anæmia, and the patient appeared to be in health.

Examination of the urinary system: There were no subjective symptoms nor any increase in micturition. Traces of albumin were present in the urine for two days after admission. Otherwise, no abnormal constituents were found. No organisms, pus cells, or epithelial cells were found in films made from the urine. From cultures a streptococcus was obtained on one occasion. The apex of the heart was 2½ in. from the mid-line and the sounds were closed. The radial artery wall was not thickened, but the pulse wave was somewhat difficult to compress. A growth of streptococci was obtained from the blood. After rest for a few days, on light diet, the urine became completely free from albumin.

The patients were visited in January, 1924. All three boys were found to be perfectly fit and working constantly as coalminers. The urine in all cases was free from albumin, blood, and casts. The daughter, Alice, was well. Her urine, also, contained no abnormal constituents. A specimen of urine from the daugher (Ellen), who was not previously examined, was obtained. This was found to contain a trace of albumin, due to a bacteriuria presumably from a pyelitis. The urine of the father was again examined and found to be free from albumin.

BACTERIOLOGICAL INVESTIGATION.

The bacteriological investigation originated in the course of the ordinary routine examination of catheter specimens sent from these cases. The initial findings of streptococci in the blood and urine of two of them suggested not only the desirability of confirming these results, but also of extending the bacteriological examination. The further observations were made in order to determine the identity and possible relationship of the streptococci isolated from the various sources, so that an opinion might be formed regarding a possible primary focus of infection.

The following method was adopted in classifying the streptococci. The hæmolytic test, used in dividing such organisms generally into two main groups, was initially applied. This was followed by division into sub-groups by Holman's method of classification,[12] in which lactose, mannite, and salicin are used in Hiss's serum-water with litmus as indicator. In regard to the use of fermentation tests in the classification of streptococci, the opinion seems to be that they lead to an unjustified multiplicity of sub-groups, which do not show any marked difference in their relation to disease processes. Like most fermentative tests, those advocated by Holman are not wholly reliable, and as tests, even in determining sub-groups, they have been found to be inadequate. Although the polysaccharide inulin is mentioned by Holman it is not included in his classification, having been mainly used by him in differentiating the pneumococcus from the streptococcus. This sugar was used for this purpose also in the present work, but in addition it was noted that the results obtained with the several strains studied served to indicate the inadequacy of Holman's classification in one direction at least. Such findings will be discussed later, but it may be mentioned that they confirm the conclusion arrived at by Logan[13] in regard to the sugar tests advocated by Holman being insufficient, and more adapted as a preliminary guide to serological tests, such as have been applied by several workers. By such means, Douglas, Fleming, and Colebrook[14] found that 24 strains of *S. pyogenes* were identical, although the sugar reactions differed. Similar observations have been recorded by Gordon.[15] This pertains to one member of the hæmolytic group, but it is possible that some members of the non-hæmolytic group, with which we are dealing in the present work, may also vary biochemically, yet be identical serologically.

Technique.

The following observations are based on the bacteriological examination of the blood, urine, and teeth in all four cases, and, in addition, the tonsils and tonsillar region in three of the cases. Blood cultures were prepared by inoculating at least 2 c.cm. of the patient's blood into flasks containing 50 c.cm. of broth. These were examined daily, and sub-cultures were made on each succeeding day up to the seventh before pronouncing them negative. From catheter specimens of urine the centrifugalised deposit was inoculated into aerobic and anaerobic media. Preparatory to inoculating tubes from the teeth and tonsils the patients were asked to cleanse the teeth and mouth, after which the tonsils and pockets in decayed teeth were swabbed. It may be noted that in all cases the teeth showed caries in the incisors and molars to a greater or less degree. With the exception of Case 4, which failed to appear at a later date, the bacteriological examination was carried out on two occasions, an interval of four months having intervened.

Results of First Examination.

A feature of the original blood cultures from Cases 1 and 4 was, that growth did not appear until the fifth and sixth day respectively. Pure growths of streptococci were obtained the following day in subculture. Similarly with the urine, delayed growth appeared on the third day of incubation and only in aerobic media. In all cases the cultures from the teeth yielded a mixed growth with streptococcal colonies in the majority. Several different-sized colonies were isolated in each case in view of the possibility of a mixed streptococcal

—	Blood.	Urine.	Teeth.
Case 1: David S.	Streptococcus.	Streptococcus.	Mixed growth with streptococcal colonies in majority.
Case 2: John S.	No growth.	No growth.	
Case 3: Joseph S.	,,	,,	
Case 4: Alice S.	Streptococcus.	Streptococcus.	

The father died of apoplexy at the age of 75, the mother died of apoplexy at the age of 68. An uncle, brother of the mother, died of apoplexy at the age of 60. A sister had acute nephritis with terminal apoplexy at the age of 51, and a brother died of chronic Bright's disease at the age of 46. Our patient had nothing abnormal in her general appearance except dilated turgid capillaries about the end of the nose. She was found to be suffering from chronic interstitial nephritis, marked arterio-sclerosis, and hyperpiesia with cardiac hypertrophy. The systolic blood pressure was 230 mm. Hg. On most days there was a trace of albumin in the urine. The specific gravity varied from 1012–1022. Reaction acid. Oxalate crystals, epithelial and red blood cells were present in the urine on admission. The amount of urine was never more than 50 oz. daily and was usually much less. The blood-urea was not increased.

The renal function tests made were as follows:—9 A.M.: 210 c.cm., 0·8 urea, 22 phenol-sulphon-phthalein (P.S.P.): 10 A.M.: 100 c.cm., 1·7 urea, 17 P.S.P. The Wassermann test was negative.

A family, composed of the father and mother, three sons and two daughters, has also recently come under our observation. Three sons and one daughter were found to be suffering from definite symptoms of renal involvement, and were admitted to hospital under our charge. The other daughter was compelled to give up attendance at school before the statutory leaving age, owing to the state of her heart and general health. There is also in this case evidence of a kidney defect.

We endeavoured to elucidate the relative significance of hereditary and acquired ætiological factors in these cases.

Question of Hereditary Factors.

Nephritis in the Antecedents.—An uncle died in the R.I.E. in 1920, from nephritis, but we have been unable to trace the record. An uncle is at present suffering from chronic nephritis. On examination of the father's urine, on one occasion only, no albumin, cells, or tube casts were present. The mother was apparently healthy.

Syphilis.—We examined the family to ascertain whether syphilis might have been a causal factor in the production of arterio-sclerosis. None of the stigmata of syphilis were present in any member of the family, and in the blood of the three sons the Wassermann test gave negative results. The blood of the daughter who presented symptoms of renal involvement was not submitted to the test. The family seems, however, to be free from all syphilitic taint.

Question of Acquired Factors.

The discovery of nephritis in four young members of one family, more or less about the same time, suggests some common acquired causal factor. It is improbable that each of the cases had a different cause. The facts relative to these matters are given in the records of the individual cases.

Although these cases of nephritis were diagnosed within a few weeks of each other, we are quite unable to say, even approximately, the dates of origin. The symptoms observed were, in fact, interpreted as exacerbations of previously existing kidney disorder, but showing no manifestations of the condition, as no previous history was obtained in any of the four patients studied.

Surroundings at Home and at Work.

The family lives in a house consisting of a room, kitchen, scullery, and lavatory. Living in this are nine persons: Father and mother, three sons (aged 20, 19, and 18), two daughters (aged 14 and 10), two lodgers (men). The house is situated in a street. The water-supply is derived from a distant reservoir and is laid on to all the houses separately in pipes (not a common pipe outside). Food is supplied by local tradesmen, and in no way differs from that supplied to other inhabitants of the street. All the male members of the family are coalminers. Work at the mine is in two shafts, the west and the south. The former contains a foot deep of water, but the temperature is moderate. The latter is dry but extremely hot, causing those working in it to become soaked in perspiration. The work of the boys is that of "drawer," and consists in hauling "hutches" back from the coal face. At the end of the trip in the south working they have to wait and are apt to get chilled after the heat. This south shaft has a bad reputation amongst miners, but on account of the heat they have to work in and not on account of any illness, other than chill, contracted while working there. Food and a bottle of water are carried by the workers. No water is obtainable at the pit for drinking, and tea cannot be made there. Symptoms pointing to renal disorder, such as are complained of by the boys, are evidently uncommon, and have not been noticed by them, or their mother, either at the mine or in the district.

Records of the Cases.

David S., aged 18, coalminer. Was admitted on May 16th, 1922, complaining of swelling of the face and pain in the head. The history was that five days before admission he caught a chill, playing football. It was learned, on further inquiry, that there had been some swelling of the face two months before the onset of the illness for which he was admitted. In infancy he had measles, and during childhood the tonsils were removed. He does not appear to have had any other illnesses. On examination his face was swollen and puffy, but not very œdematous. His complexion was pasty. He had no marked anæmia. Examination of the urinary system showed the presence of albumin, blood, and casts—albumin about 10 g. per litre. The casts were chiefly composed of broken-down epithelium and blood cells. Streptococci were isolated from the urine on three occasions. (No subjective symptoms were complained of.) The non-protein nitrogen of the blood was 42 mg. per 100 c.cm. The urea concentration in the second hour was 1·7 per cent. The P.S.P. excretion was high—95 per cent. being returned in two hours.

Renal efficiency tests, June 28th, 1922:—First hour: 270 c.cm., 1·1 per cent. urea, 60 per cent. P.S.P.; second hour: 113 c.cm., 1·7 per cent. urea, 35 per cent. P.S.P.

The heart was somewhat enlarged, the apex being 4¼ inches from the middle line. Diffuse pulsation was seen in the fourth and fifth intercostal spaces, and the movement was heaving in character. The heart sounds were closed. The radial artery was definitely palpable, and the systolic blood pressure (taken on May 21st) was 172 mm. Hg. Blood culture yielded a growth of streptococci on one occasion. Ten teeth were present in each jaw. These were carious and in a septic condition. The breath was rather foul. There was no congestion of the fauces. A mixed growth of organisms was obtained from the teeth and tonsillar region, with streptococci preponderating. The Wassermann reaction was negative.

The patient was first put on a salt-free diet, and later on light diet. Daily hot-air baths were given. The further course was that the œdema gradually disappeared; the albuminuria was somewhat obstinate, ranging during the first eight days from 6 to 15 g. per litre, dropping gradually to 1 g. per litre, and remaining at this. Hæmaturia occurred on ten occasions, and ceased shortly before his discharge from hospital in the early part of August. Blood, epithelial cells, and granular casts were noted once. When we saw him again by request, four months after his discharge from hospital (seven months after admission), a mere opalescence appeared on heating the urine, and streptococci were obtained in cultures. The S.B.P. was 126, and the apex beat of the heart was 3½ inches from the mid-line. He had been at work since his discharge and had felt entirely well.

John S., aged 20, coalminer, was admitted to hospital on June 6th, 1922. Complaint: Swelling of face; pain in back; headache, which had been present four days. He had worked in both the wet and the hot shafts—in the latter he worked stripped to the waist, and he had only worked nine days there when he was taken ill. He consulted his doctor, who sent him to hospital. The only previous illness of any importance was osteomyelitis ten years previously, when part of the right tibia was removed. He had not required medical attendance in recent years. He had not had scarlet fever. There was no history of previous attacks of nephritis. On examination, his face was puffy around the eyes but not very œdematous.

Examination of the urinary system: No subjective symptoms were complained of. The urine was passed in good quantities (1136–1845 c.cm. per diem). Traces of blood were present, and albumin to the extent of 4 g. per litre. Granular and hyaline casts were present, but no organisms, pus, or epithelial cells were found in a stained film. No growth was obtained on culture. The non-protein nitrogen of the blood was 36 mg. per 100 c.cm. The urea concentration in the second hour was 2·3 per cent.

The P.S.P. excretion was not good, 50 per cent. being returned in two hours. First hour: 183 c.cm., 1·4 per cent. urea, 35 per cent. P.S.P.: second hour: 106 c.cm., 2·3 per cent. urea, 15 per cent. P.S.P. A blood count showed some leucocytosis.

The apex of the heart was 3¾ in. from the mid-line. There was a slight systolic murmur at the mitral area, but no accentuation of the second sound. No subjective symptoms were complained of. The wall of the radial artery was definitely palpable. The arterial wave was slow in upstroke and downstroke and well sustained, the vessel was not easily compressed. The systolic blood pressure was 148 mg. Hg. No growth was obtained from blood cultures on two occasions. The fundus oculi showed no changes. Six teeth were in bad condition, but there was no pyorrhœa alveolaris. The tongue was slightly furred: the fauces healthy. The Wassermann reaction was negative.

The patient responded to treatment more quickly than in the last case, the blood disappearing from the urine and the albumin diminishing to a trace. Four months after leaving hospital the urine was completely free of albumin, the S.B.P. was 142 mm. Hg (the arteries were very definitely palpable), œdema was absent, and no subjective symptoms were complained of. Stained films of the urine were bacteriologically negative.

Joseph S., aged 19, coalminer, was admitted to hospital on June 26th, 1922, as we wished to examine as many members of the family as were willing to present themselves. He had been unemployed for a fortnight previous to admission, but had felt fit and well. Before this he had worked in both shafts. Complaint: Swelling of the face, commencing one week before admission, but of no other symptoms. On examination, patient showed some puffiness under the eyes, but he did not feel ill in any way. The swelling had been present for one week. He could remember no illness, even during childhood. Examination of the urinary system showed slight frequency of micturition—he had to rise once during the night. The quantity per diem was 994–1278 c.cm. The urine itself showed a trace of blood, and albumin to the extent of 1 to 3 g. per litre. Hyaline casts, red blood corpuscles, and epithelial cells were found in the deposit. Cultural examination was negative.

On July 10th the non-protein nitrogen of the blood was 38 mg. per 100 c.cm. Urea concentration in the second hour was 2·6 per cent. P.S.P. elimination good, at 80 per cent. in two hours. First hour: 73 c.cm., 2·3 per cent. urea, .45 per cent. P.S.P.; second hour: 82 c.cm., 2·6 per cent. urea, 35 per cent. P.S.P.

Examination of the circulatory system revealed no subjective symptoms. The heart was somewhat enlarged, the apex being 4¼ in. from the mid-line—it was forcible in character, though not increased in extent. The wall of the radial artery was definitely palpable. Systolic blood pressure was 172 mm. Hg. No growth was obtained from blood cultures. Teeth were in fair condition and gums healthy. Tonsils not enlarged. Wassermann reaction of the blood negative. In cultures from teeth and tonsils streptococcal colonies were numerous.

Patient responded well to treatment, and showed a decrease of blood pressure to 143 mm. Hg and the albumin and blood in the urine diminished to a trace. A few well-formed granular casts were present on one occasion. On examination four months after leaving hospital there was only a faint trace of albumin in the urine, the heart had diminished in size, the apex being 3½ in. from the mid-line, the first sound was dull and the second slightly accentuated, the S.B.P. was 139, and the arterial wall palpable.

Alice S., aged 10. It was heard that this girl was suffering from some urinary trouble, and she was sent for and admitted to hospital. It appeared that six months previously she had some pain in the right iliac fossa, and she was then seen in the Royal Hospital for Sick Children. There she was X rayed and told there was "something growing round the kidney." She had had measles. On admission, there was no anæmia, and the patient appeared to be in health.

Examination of the urinary system: There were no subjective symptoms nor any increase in micturition. Traces of albumin were present in the urine for two days after admission. Otherwise, no abnormal constituents were found. No organisms, pus cells, or epithelial cells were found in films made from the urine. From cultures a streptococcus was obtained on one occasion. The apex of the heart was 2½ in. from the mid-line and the sounds were closed. The radial artery wall was not thickened. but the pulse wave was somewhat difficult to compress. A growth of streptococci was obtained from the blood. After rest for a few days, on light diet, the urine became completely free from albumin.

The patients were visited in January, 1924. All three boys were found to be perfectly fit and working constantly as coalminers. The urine in all cases was free from albumin, blood, and casts. The daughter, Alice, was well. Her urine, also, contained no abnormal constituents. A specimen of urine from the daugher (Ellen), who was not previously examined, was obtained. This was found to contain a trace of albumin, due to a bacteriuria presumably from a pyelitis. The urine of the father was again examined and found to be free from albumin.

BACTERIOLOGICAL INVESTIGATION.

The bacteriological investigation originated in the course of the ordinary routine examination of catheter specimens sent from these cases. The initial findings of streptococci in the blood and urine of two of them suggested not only the desirability of confirming these results, but also of extending the bacteriological examination. The further observations were made in order to determine the identity and possible relationship of the streptococci isolated from the various sources, so that an opinion might be formed regarding a possible primary focus of infection.

The following method was adopted in classifying the streptococci. The hæmolytic test, used in dividing such organisms generally into two main groups, was initially applied. This was followed by division into sub-groups by Holman's method of classification,[12] in which lactose, mannite, and salicin are used in Hiss's serum-water with litmus as indicator. In regard to the use of fermentation tests in the classification of streptococci, the opinion seems to be that they lead to an unjustified multiplicity of sub-groups, which do not show any marked difference in their relation to disease processes. Like most fermentative tests, those advocated by Holman are not wholly reliable, and as tests, even in determining sub-groups, they have been found to be inadequate. Although the polysaccharide inulin is mentioned by Holman it is not included in his classification, having been mainly used by him in differentiating the pneumococcus from the streptococcus. This sugar was used for this purpose also in the present work, but in addition it was noted that the results obtained with the several strains studied served to indicate the inadequacy of Holman's classification in one direction at least. Such findings will be discussed later, but it may be mentioned that they confirm the conclusion arrived at by Logan[13] in regard to the sugar tests advocated by Holman being insufficient, and more adapted as a preliminary guide to serological tests, such as have been applied by several workers. By such means, Douglas, Fleming, and Colebrook[14] found that 24 strains of *S. pyogenes* were identical, although the sugar reactions differed. Similar observations have been recorded by Gordon.[15] This pertains to one member of the hæmolytic group, but it is possible that some members of the non-hæmolytic group, with which we are dealing in the present work, may also vary biochemically, yet be identical serologically.

Technique.

The following observations are based on the bacteriological examination of the blood, urine, and teeth in all four cases, and, in addition, the tonsils and tonsillar region in three of the cases. Blood cultures were prepared by inoculating at least 2 c.cm. of the patient's blood into flasks containing 50 c.cm. of broth. These were examined daily, and sub-cultures were made on each succeeding day up to the seventh before pronouncing them negative. From catheter specimens of urine the centrifugalised deposit was inoculated into aerobic and anaerobic media. Preparatory to inoculating tubes from the teeth and tonsils the patients were asked to cleanse the teeth and mouth, after which the tonsils and pockets in decayed teeth were swabbed. It may be noted that in all cases the teeth showed caries in the incisors and molars to a greater or less degree. With the exception of Case 4, which failed to appear at a later date, the bacteriological examination was carried out on two occasions, an interval of four months having intervened.

Results of First Examination.

A feature of the original blood cultures from Cases 1 and 4 was, that growth did not appear until the fifth and sixth day respectively. Pure growths of streptococci were obtained the following day in subculture. Similarly with the urine, delayed growth appeared on the third day of incubation and only in aerobic media. In all cases the cultures from the teeth yielded a mixed growth with streptococcal colonies in the majority. Several different-sized colonies were isolated in each case in view of the possibility of a mixed streptococcal

—	Blood.	Urine.	Teeth.
Case 1: David S.	Streptococcus.	Streptococcus.	Mixed growth with streptococcal colonies in majority.

Case 4: Alice S.	Streptococcus.	Streptococcus.	

infection of hæmolytic and non-hæmolytic types. In applying the hæmolytic test, however, all the organisms proved to be of the non-hæmolytic variety.

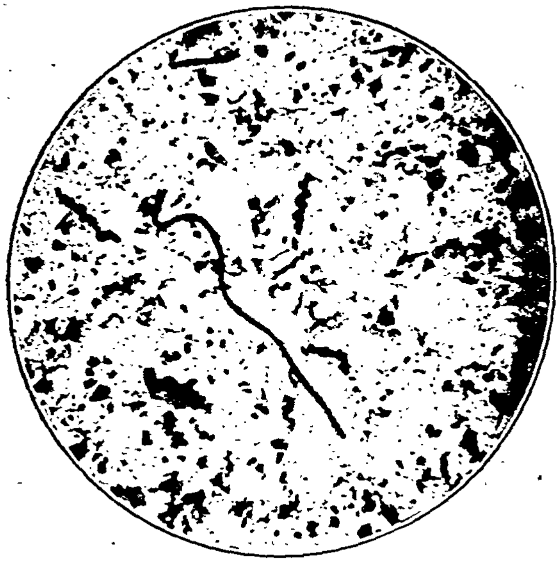
Results of Second Examination.

In regard to the second series only three cases were examined, the tonsils and tonsillar region being included. The original blood cultures in broth, and the succeeding sub-cultures made each day up to the seventh, remained negative and sterile. The urine in Case 1 again gave a pure though scanty growth of streptococci on the third day of incubation, the others remaining negative and sterile. The cultures from the tonsils in each case produced a mixed growth with streptococcal colonies in the majority. Individual colonies were tested as with those from the teeth, and were found to be of the non-hæmolytic type. The appearance of the growth in all the strains isolated was practically identical. All behaved similarly in producing an obvious greenish colouration by the hæmolytic test, and none showed definite hæmolysis; they were thus identified as of the non-hæmolytic, or viridans group, of which most members are regarded as saprophytic. They were differentiated from the pneumococcus by the bile-solubility test, by which means all were proved to be insoluble. Morphologically, they varied only in minor details, all of them showing a tendency to diplococcal formation in short chains.

—	Blood.	Urine.	Teeth.
Case 1 : David S.	No growth.	Streptococcus.	Mixed growth with streptococcal colonies in majority.
Case 2 : John S.	,,	No growth.	
Case 3 : Joseph S.	,,	,,	

The sub-groups were classified according to Holman's method already described. The purity of each strain was previously determined by microscopic examination before inoculations of the sugars were made. The readings were noted daily for one week, and in most instances were based on the results of at least two separate series of sugar tests with each of the organisms. More recent results, which showed departure from the original reactions, are also included for reasons to be discussed later.

FIG. 1.



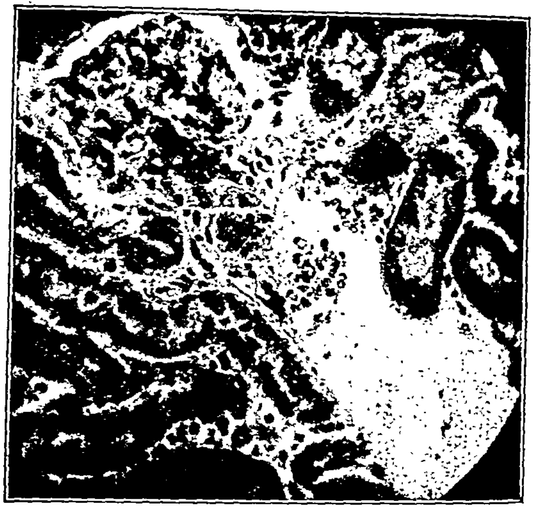
To show numerous tube casts in urine of rabbit which died of acute nephritis.

The streptococci isolated belong to the saprophytic group. The two types *S. mitis* and *salivarius* commonly live as harmless saprophytes in the mouth and throat, but may become pathogenic in certain circumstances. Their immediate interest here lies not only in their prevalence in the teeth and tonsils, but also in the possible relationship of the streptococci in these situations to their occurrence in the blood and urine of two of the cases.

These sub-groups of non-hæmolytic streptococci have been classified by their sugar reactions meantime, the reliability of which is much in question at the present time. The importance of such a division is considered more academic than real,[16] and of no great consequence from the point of view of their relation to disease.

The differentiation between *S. mitis* and *salivarius* depends on their behaviour towards salicin, in which sugar it has not been constant. One strain conformed to *S. mitis* and another to *S. salivarius* on the first two occasions. In tests repeated several times subsequently and on recent dates they interchanged their identity, judging entirely from their reactions in salicin. That the sugar was not inert, or the organisms dead, were verified by the reactions of the other strains in the same batch of salicin, by microscopic examination and by sub-culture. Their reaction in inulin was also noted in which two strains of *S. mitis* and one of *S. salivarius* gave a positive reaction. On this latter feature, other characters being absent, Holman considers such organisms as inulin-fermenting varieties of their respective types. A similar inference suggests itself in the present case to account for the irregular reactions in salicin, in that one might be merely a variant of the other; and as with some specimens of *S. pyogenes* which differed in their behaviour towards mannite, yet were found to be serologically identical, so it may conceivably be in the present instance with *S. mitis* and *salivarius* that, though differing biochemically, they may be the same serologically.

FIG. 2.



Section of rabbit's kidney, showing œdema, hæmorrhage, and acute tubular changes. Animal died in five days.

The results of the investigation generally, apart from the question of academic points, present features of a suggestive nature. These features become more interesting, however, if the one organism may be considered a variant of the other. Whether this be so or not has not yet been determined, but it will suffice for the present purpose to note that they are of the non-hæmolytic group, and to consider their characters in this respect. Such streptococci closely associate themselves with chronic streptococcal infections, possess high power of invasion, and tissues in a state of low resistance are attacked by them. They stimulate little reaction on the part of the body, and apparently render the tissues more susceptible to reinfection with a fatal issue only after a prolonged course or repeated reinfections. They give rise to tonsillitis of a relatively mild form. Both *S. mitis* and *salivarius* have occasionally been found in pathological conditions in the blood and in endocarditis. In addition to other toxic agencies it is stated by MacCallum that streptococcal infections, especially protracted subacute infections with *S. viridans*, to which group the above organisms belong, may cause a glomerulo-nephritis with consequent destruction of the whole glomerular structure.

It is significant that the streptococci found in the blood and urine are not only closely allied, but may possibly be biologically identical with those isolated from the teeth and tonsils, and that they are of the group associated with subacute infections, into which category the four cases may be classed.

EXPERIMENTAL OBSERVATIONS. BY DR. BUCHANAN.

The association of non-hæmolytic streptococci with certain of the cases of subacute nephritis recorded above, suggested to one of us (G. B.) a general investigation into the rôle played by such streptococci in the production of experimental nephritis in rabbits. This work is at present in progress. It is the intention of this communication merely to indicate the nature of the experiments and such results as bear upon the problem of the causation of nephritis. The investigation when completed will form the subject of an independent paper.

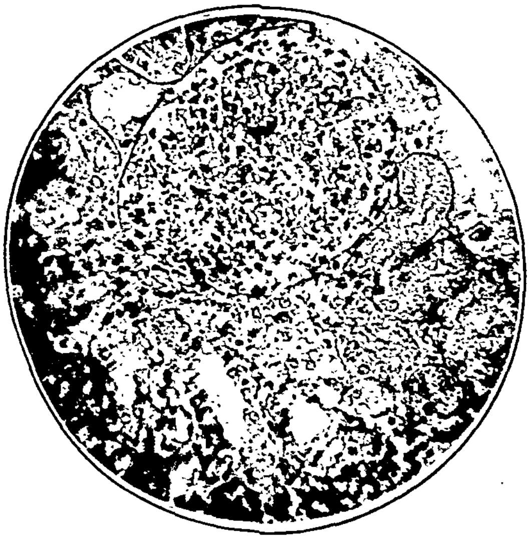
The strains of streptococci isolated from the earlier cases studied by us unfortunately died out before a licence for animal experiments was granted. Other cases of subacute nephritis were, however, investigated later, and from two of them a pure growth of a non-hæmolytic streptococcus was obtained from catheter specimens of urine. The two organisms conformed biochemically to *S. fæcalis*. These were used for experimental purposes.

The animals selected for this work were kept under observation for one week before beginning the experiments. Only those whose urine was entirely free from albumin and other evidence of renal trouble were used.

The nature of the experiments consisted in a study of the effects produced on the function and structure of the kidney by the following agencies: (1) Cold and damp; (2) cold and damp, plus streptococcal blood infection: (3) streptococcal blood infection.

The method used in determining the effects of cold and damp was that adopted by Cicconardi,[17] in which a freezing mixture is applied to the dorsum in the region of the kidneys. The object in the present work was to ascertain if the influence of local chilling, as a predisposing factor, rendered the kidney more susceptible to injury by the action of the circulating streptococci. The repeated daily chilling, applied for one hour, constantly lowered the rectal temperature 2° C., but urinary examination revealed no abnormal constituents. No very marked alteration in kidney structure was noted in chilled animals chloroformed at varying intervals. The introduction of repeated doses of streptococci into the circulation after chilling has so far not given uniform results. It was thought at first that the chilling induced a more rapidly fatal issue, but later it was found that the injection of streptococci alone was as rapidly fatal in some instances, and produced almost similar kidney lesions.

FIG. 3.

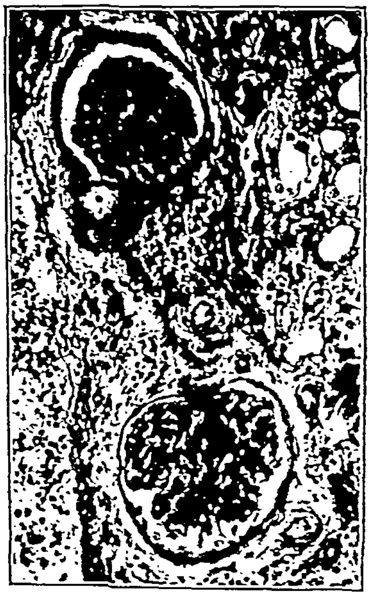


Section of rabbit's kidney showing acute glomerulo-nephritis and tubular degeneration. Animal died in seven days.

It will meet the present purpose to state briefly that as a result of the intravenous injection of the non-hæmolytic streptococcus, *S. fæcalis*, into rabbits symptoms of acute nephritis were produced. Albumin in considerable quantity appeared in the urine within the first week after inoculation. In some cases it increased daily in amount, and persisted until the animals died. In other instances where the animal survived for a longer period the albumin decreased and almost disappeared. Microscopically (Fig. 1) the urines of these animals invariably showed abundant tube casts, chiefly hyaline in nature, although granular, epithelial, and blood forms were also present. Red cells and epithelial cells were very numerous.

In some animals which succumbed shortly after inoculation the post-mortem examination showed an accumulation of fluid in the pericardial sac and abdominal cavity. This appeared to be a result of the nephritis; no evidence of pericarditis or peritonitis was observed. In such cases the kidney presented the typical microscopical changes associated with acute diffuse nephritis. Particularly marked was the degree and extent of the œdema, which is shown in Fig. 2. In animals which survived for longer periods the kidney showed progressive degenerative changes, chiefly in the glomeruli (Fig. 3) and Bowman's capsule (Fig. 4). Accumulations of lymphoid cells also became prominent in areas affected by hæmorrhage and œdema. The accompanying micro-photographs illustrate the changes referred to above.

FIG. 4.



Section of rabbit's kidney showing marked thickening of Bowman's capsule. Stained by Mallory's method.

SUMMARY.

1. That nephritis may be hereditary, familial, or congenital is shown well in the families described by Hurst and others.

2. It would seem that a familial predisposition to nephritis exists in a series of cases instanced by us and notably in two families.

3. In one family there was an association of apoplexy and nephritis, six members of the family being affected by one or both. The discovered onset was at or after middle life.

4. In the second family there were seven cases, of which five were discovered in childhood or adolescence. Four of the cases in this family were diagnosed within a few weeks of one another. That the actual origin was not recent, but of some years' standing, is evident from the fact that the arteries in three were thickened, the blood pressure high, and the non-protein nitrogen of the blood high.

5. No definite ætiological factor could be found in these cases to account for either the nephritis, high blood pressure, or thickened arteries. Syphilis is discounted by a negative Wassermann reaction in all cases. There is no history of scarlet fever or influenza in any of the cases.

6. In one case there is a definite history of chill immediately preceding the onset of the disease.

7. Pure growths of non-hæmolytic streptococci were obtained from the blood and urine of two cases on admission to hospital.

8. Blood cultures carried out four months later yielded no growth.

9. A streptococcus was obtained twice from the urine of one case while in hospital, and again on his return for a later examination.

10. A feature of note in primary cultures was the delay and feeble nature of the growth, which only appeared between the third and sixth day of incubation.

11. The types of streptococci isolated from the blood and urine were biochemically identical with those obtained from the teeth, tonsils, and tonsillar region. Such streptococci commonly live as harmless saprophytes in the mouth and throat, but may become parasitic and associate themselves with subacute infections.

12. In addition to the presence of intrinsic weakness causing a "locus minoris resistentiæ" in the kidney, a possible extrinsic factor in the recurrent attacks of nephritis may possibly be due to streptococcal infections.

13. There is considerable evidence for the conclusion that the teeth and tonsils may be regarded as among the important primary sources of infection, and probable portals of entry for hæmatogenous infection. It is possible that repeated infections may occur at such times when the normal resistance of the tonsils and tissues is lowered from local or general causes. Such infections may exercise an exacerbating influence in the course of the disease.

14. The failure to confirm the result of the first bacteriological examination of the blood, and the negative findings in two of the cases, suggest a focal infection producing disease by periodic systemic invasion—that is, a transient bacteræmia with rapid localisation of the invading organism in such organs most susceptible to its power of invasion, resulting in a focal expression of infection. In the family studied the kidney appears to be singularly predisposed to infection and the most susceptible organ.

15. Experimental evidence is given on the causation of nephritis by a non-hæmolytic streptococcus isolated from cases of subacute nephritis.

GRADUATED EXERCISE IN PULMONARY TUBERCULOSIS.

By H. O. BLANFORD, M.B., B.S. Lond.,
LATE MEDICAL SUPERINTENDENT, KING EDWARD VII. SANATORIUM, MIDHURST.

During the years 1920, 1921, and 1922 graduated exercise was employed as a form of treatment at King Edward VII. Sanatorium in 624 cases of pulmonary tuberculosis. Table I. shows the results from the replies to inquiries sent out in 1924; Table II. shows the cases classified according to the Turban-Gerhardt classification; while Table III. gives the result of treatment according to the stage of the disease.

The fact that 78·1 per cent. of Group 1 cases and 53·7 per cent. of Group 3 cases are well emphasises the importance of early diagnosis and treatment. The death-rate of cases in Group 1 (5·3 per cent.) compared with the death-rate of cases in Group 3 (26·3 per cent.) has equal significance.

Not all the cases admitted to and discharged from the sanatorium in these years are included in the following tables, and in this sense the cases recorded are to be regarded as picked cases, inasmuch as only those cases were allowed to attempt any graduated exercises whose condition appeared to justify it, and only those cases are included whose condition and response enabled them to reach the higher grades. In considering the results of a particular form of treatment it has appeared reasonable only to include those patients who had actually experienced that treatment.

The theory of auto-inoculation has been the controlling principle in the graduation of the exercise, and the relation between toxic absorption and muscular action has been constantly controlled and observed.

Table I.—*Showing Results from Replies to Inquiries Sent Out in 1924.*

Symptoms which have been regarded as an indication of an excessive toxic absorption have been the following: an evening rise of temperature above 99° F. oral, slight headache, increase of cough and sputum, excessive fatigue, loss of appetite, aching in back or limbs, and general malaise. Table IV. shows the numerical occurrence of such symptoms and also shows that, as might be expected, the incidence increases as the stage of the disease advances.

Table IV.—*Showing Numerical Occurrence of Symptoms regarded as an Indication of Excessive Toxic Absorption.*

Group 1: Of 243 cases 73, or 30 per cent.
Group 2: Of 206 cases 80, or 39 per cent.
Group 3: Of 175 cases 92, or 53 per cent.

The maximum temperature recorded was 104·8° F., but this was exceptional, the rise usually observed being about 100°. The maximum number of such reactions to occur in any one case was nine. These reactions when observed were controlled by absolute rest in bed until the evening temperature returned to a normal level and the symptoms subsided, and the patient looked and felt well. He then returned by gradual stages to the grade of exercise which had caused the reaction. The maximum period for which an individual was kept on absolute rest was 21 days, and the shortest time taken to return to a grade of exercise after a reaction was three days. It is of interest to note that many cases of raised temperature accompanied by symptoms of toxæmia occurred immediately after admission to the sanatorium following the exertion of the journey, and also that the majority of the reactions occurred during the earlier stages of the treatment—e.g., walks of a mile or two, or the lighter grades of garden work.

Only those cases have been recorded as reactions which were immediately related to an increase of exercise and were accompanied by the usual symptoms of excessive toxic absorption. Rises of temperature which might be explained by other causes—e.g., dental trouble, constipation, or premenstrual rises—have not been included.

The grades of exercise progress from absolute rest in bed or no exercise at all, to being in bed all day but not on absolute rest, to being up for increasing periods during the day, to taking an increasing amount of walking exercise, and, only when the individual progress and condition permit, to exercises in gardens and grounds and recreations involving exercise such as golf.

All exercise is prescribed and carried out under close medical supervision. This is essential, not only n order to observe how each individual is responding, but also to prevent the prescription being exceeded. A non-medical supervisor is apt to regard the necessity of the work to be done as more important than the medical requirements of any particular case.

The attitude of mind referred to as "spes phthisica" is frequently marked in the later stages of the disease and is usually a bad prognostic feature. *It is conspicuous by its absence in the* earlier stages, a spirit of moroseness and depression being far more frequently observed. A significant feature of successfully conducted graduated exercise is the way in which a patient's cough and sputum diminish, the temperature excursions and variations become less marked, and depression gives way, not to a groundless hopefulness, but to a cheerful alertness, so that the individual's nature seems to have undergone an entire change for the better.

THE USE OF INSULIN IN OPERATIONS ON THE DIABETIC.

By H. S. PEMBERTON, M.B. LIVERP., M.R.C.P. LOND.,
PHYSICIAN TO THE DAVID LEWIS NORTHERN HOSPITAL, LIVERPOOL;
AND
L. CUNNINGHAM, M.B. CAMB., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO THE HOSPITAL.

ALTHOUGH the more recent dietetic methods of Allen and Joslin[1] have already begun to diminish the mortality following surgery in the diabetic, the use of insulin in selected cases seems to remove the risks altogether. These risks are, briefly, the liability to post-operative infection and the event of coma, and are mainly due to anæsthesia and shock, both of which produce the hyperglycæmia, the control of which is the main aim of management. In operations on the non-diabetic ether anæsthesia produces hyperglycæmia, glycosuria,[2] and a lowering of the alkali reserve.[3] In two cases which we investigated results were obtained as given in Table I. (values expressed as mg. per 100 c.cm. blood).

TABLE I.

—	Length of ether administration.	Arterial glucose.	Venous glucose.
1	15 mins.	110	100
2	40 mins.	171	150

It will be noted that the arterial value is higher than the venous, which we attribute to increased glycogenolysis in the liver.

In operations on the diabetic the rise in blood-sugar and the fall in alkali reserve are both greater, and, moreover, the glucose value of venous blood tends to become greater than that of the arterial blood, a condition which we have found to occur repeatedly in severe and untreated diabetics. This is shown in the following case (Table II.) which was operated on for umbilical hernia. Insulin was not used.

TABLE II.

Period.	Arterial glucose.	Venous glucose.	CO_2 vols. per cent.
Before operation	—	99	57
After ether induction—			
10 mins.	201	150	44·8
30 mins.	294	315	45·9
60 mins.	281	301	45·9

As will be shown below, insulin decreases ether-hyperglycæmia, but does not always succeed in producing what appears to be the typical insulin effect of raising the value of the glucose of arterial blood above that of the venous blood. Even after the administration of insulin the hyperglycæmia continues for several days, the length of time depending upon the original severity of the case, length and severity of the operation, and upon the occurrence of post-operative complications. Even when we have controlled the hyperglycæmia during operation we have found that it has subsequently been reproduced by post-operative sepsis; in support of this we have the figures of Joslin[4] for cases occurring in the Massachusetts General Hospital from 1913 to 1918. Here the mortality of diabetics with infection was 50 per cent., and without infection 12 per cent. The

alkali reserve also remains low for several days unless alkalis are administered.

Technique.

The technique which we employed may be divided into the following stages.

1. *Preparation Before Operation.*—For this at least a week appears to be necessary, during which hyperglycæmia and acidosis are removed and the patient is brought into nitrogenous equilibrium by appropriate diet and insulin dosage which naturally varies in each case. We did not attempt to fill the liver with glycogen as advocated by Joslin[5] and Barborka.[6] No food was given on the day of operation, half an hour before which 10 units of insulin were given.

2. *During Operation.*—Ether was invariably employed as an anæsthetic and was administered by the open method. Blood was removed simultaneously from the radial artery and median basilic vein at intervals of 20 minutes. Half an hour after the induction of anæsthesia insulin was given in amounts varying with the nature of the case.

3. *After Operation.*—This appears to be the most critical period. The patient was put on a milk diet, and the dosage of insulin governed by the magnitude of the post-operative hyperglycæmia. In post-operative infection either in the wound or arising from pulmonary conditions the reduction of hyperglycæmia presented great difficulty. A low post-operative alkali reserve may be effectively removed by alkalis as in Case 1.

The method used for the determination of glucose in the blood was the one described by Folin and Wu.[7] The carbon dioxide combining power of the blood was estimated by Van Slyke's method.[8] Diets used are in accordance with a simple scheme devised by one of us.[9] Operations were performed by Mr. G. C. E. Simpson and Dr. Leith Murray. Ether was administered by the open method preceded by the usual hypodermics.

Summary.

Ether anæsthesia in the diabetic produces a more severe hyperglycæmia and a greater fall in the alkali reserve than in a non-diabetic. They may be controlled by the pre-, intra-, and post-operative use of insulin. In spite of the administration of insulin the post-operative complication of sepsis appears to maintain both hyperglycæmia and a low alkali reserve; the latter may be restored by alkali therapy.

A CASE OF
METASTATIC GAS GANGRENE
IN CIVIL PRACTICE.

BY J. R. LEARMONTH, M.B., CH.B. GLASG.,
EXTRA DISPENSARY SURGEON, WESTERN INFIRMARY, GLASGOW.*

THE following case presents a clinical picture so rare as to merit publication.

C. W., a coalman, aged 35, was admitted to the Western Infirmary, Glasgow, on March 21st, 1924. He stated that he had swung himself up on his lorry while it was in motion, whereupon he was seized immediately with epigastric pain so severe that he fell upon the pavement, where he remained until the arrival of the ambulance which brought him to the infirmary. On admission the temperature (rectal) was 99·2° F., the pulse 118, and the respirations 24. The whole abdomen was board-like in its rigidity and exquisitely tender. The patient was in great agony and collapsed. There was no vomiting. It was found that for two years he had suffered at intervals from epigastric pain, which occurred shortly after meals; he had rarely vomited. The gastric symptoms had never been so severe as to force him to consult a doctor. A slight degree of constipation had been present for the same period.

A diagnosis of perforation of a gastric ulcer was made, and without delay I opened the abdomen through the upper part of the right rectus muscle. The peritoneal cavity contained a considerable quantity of turbid, straw-coloured fluid, which was removed with gauze sponges as completely as possible. Examination showed that the lesser curvature of the stomach, rather towards its pyloric end, was occupied by a large saddle-shaped ulcer. Attached to the peritoneum over the anterior half of this ulcer was a mass of partially organised fibrin about 2 inches in diameter, and in form like the top of a mushroom turned upside down. More recent adhesions bound this mass to the anterior edge and under surface of the left lobe of the liver. Tunnelling through its middle was a perforation which admitted the tip of the little finger. Invagination of the perforated ulcer was impossible owing to the presence of the bulky mass of fibrin; temporary drainage of the peritoneal cavity seemed insufficient in view of the length of the perforating passage and the hard unyielding character of its walls, so that primary V-shaped resection of the whole ulcerating area was decided upon as the only hopeful line of treatment. This was performed as rapidly as possible, silk being used for the outer Lembert suture and catgut for the inner suture. The incision was closed in layers without drainage, and a tube containing a gauze wick was placed in the recto-vesical pouch through a separate median suprapubic stab wound.

At the close of the operation the condition of the patient was very grave. On his return to the ward a pint of saline solution was administered by the rectum, and strophanthin gr. 1/250 was injected hypodermically; rectal salines (10 oz.) and strophanthin, gr. 1/250, were ordered to be given every four hours. On the following day the patient was still very ill—temperature 101·8° F., pulse 156, respirations 36. On the second morning after operation, however, his condition was markedly improved. The temperature was 99·2°, the pulse 112; and the respirations 28. The dose of strophanthin was reduced to gr. 1/250 every six hours. The improvement was well maintained throughout the day, but about midnight he complained of pain in his right upper arm, and the pulse-rate rose to 120. Examination showed a diffuse reddening of the outer wall of the right axilla, to which a wet dressing was applied. By the morning of the third day the temperature had risen to 102°, the pulse to 140, the respirations to 32, and he was slightly jaundiced. His general condition was obviously hopeless. Examination of the right arm revealed a diffuse swelling extending along the inner aspect of the arm from about 3 inches above the level of the elbow-joint to the apex of the axilla. The skin over this area was a dusky purple colour and insensitive and crepitation could be elicited over its whole extent. Two parallel longitudinal incisions were made throughout the whole length of the swelling; these allowed the escape of gas under considerable tension. The muscles on the inner aspect of the arm were pale, quite necrotic, and riddled with gas bubbles. The wounds were swabbed out with peroxide of hydrogen, and a wet dressing was applied.† The patient died at 1 P.M., exactly 72 hours after the perforation of his ulcer; he had exhibited to a marked degree the retention of mental faculties found in this type of infection.

Bacteriological Report.

A portion of the necrotic material from the arm, obtained during life, was examined in the clinical laboratory of the Western Infirmary by Dr. E. M. Dunlop, who reported:—

"No growth was obtained on aerobic cultures. Under anaerobic conditions a growth of a Gram-positive bacillus was obtained, and this culture, when plated, yielded abundant colonies which, macroscopically, were all of the same type. Twelve of these were subcultured in litmus-milk, and in each instance the characteristic "stormy" fermentation associated with *B. welchii* was obtained after a short period of incubation. In deep glucose-agar shake cultures the organism grew rapidly, and led to abundant gas production. Films made from the various cultures were examined; in each case the growth appeared to be pure, and the organism had the microscopic characters of *B. welchii*. It grew only

[*] During the tenure of a grant from the Medical Research Council.

[†] Messrs. Burroughs, Wellcome and Co. inform me that they have still in stock antitoxic serum for administration in cases of gas gangrene due to *B. welchii*. As this serum was prepared some years ago they naturally do not guarantee its potency, but it might prove useful in such an emergency as described above.

under anaerobic conditions, and exposure of surface cultures to the air for a few hours was found to prevent growth on subsequent anaerobic subcultures. Spore formation has not been observed, and attempts to produce it have been unsuccessful."

Post-mortem Examination.

At the necropsy, performed by Dr. J. W. S. Blacklock 24 hours after death, the muscles on the inner side of the right upper arm were found to be necrotic. Numerous small gas cavities were present, and these extended into the tissues on the right side of the neck. Dissection revealed no evidence of embolism or thrombosis in the brachial artery or in its main branches in this region. The abdominal surgical incisions were healthy. A slight degree of plastic peritonitis was present, the coils of bowel being irregularly congested and matted together by fibrinous lymph. No leakage was found at any part of the repair of the stomach, and this wound appeared to be healing normally. The intestine showed no gross morbid change. The liver showed some fatty change, and small bubbles of gas could be expressed from the branches of the portal vein. The spleen was enlarged (weight 9 oz.), dark red, and firm. Slight fatty changes were present in the kidneys, which were otherwise healthy. The pericardial sac contained a small quantity of blood-stained fluid. The heart wall showed cloudy swelling and the endocardium was deeply stained with hæmoglobin. All the valves were healthy and competent. The intima of the aorta was deeply stained with hæmoglobin. The lungs showed well-marked recent venous congestion. In smears from the muscles of the arm were found large numbers of an organism morphologically resembling *B. welchii*, together with cocci. Culture of the muscle anaerobically showed the former organism. Smears and cultures from the spleen demonstrated the presence of an organism morphologically resembling *B. welchii* in practically pure culture. (The organisms other than *B. welchii* were doubtless due to post-mortem contamination—see bacteriological report on tissue obtained during life.) On section the gastric ulcer proved to be of the chronic inflammatory type. Some attempt at healing was present, and at one part of the base of the ulcer more recent acute inflammatory change was found.

Comment.

Gas gangrene is but rarely encountered in civil surgery; Christopher (1922)[1] found nine cases recorded by seven writers. Almost all the cases fall into two groups. In the first group gas gangrene occurs as a complication of various forms of injury sustained under conditions favouring infection from the soil. In the second group it follows septic abortion. Its occurrence has also been noted in the scrotum,[2] in the gall-bladder,[3] and as a complication of ischio-rectal abscess.[4]

The most unusual feature of the case reported is the metastatic nature of the gangrenous focus. Septicæmic and pyæmic manifestations in infections by gas-producing bacilli are to be regarded as complications of what is usually a local process which causes a profound toxæmia; although invasion of the blood by the causative organisms rapidly occurs after death. On the other hand, gas production is not uncommonly seen post mortem in the organs of subjects dying of other diseases; in these cases the bacilli enter the blood after death from the bowel, of which they are normal inhabitants. It is necessary in such cases to be cautious in assigning ætiological value to the results of examinations of material obtained in the post-mortem room.

Cases of metastatic gas gangrene following war wounds have been recorded.[5] The factors determining the sites of secondary foci appear to be slight local injury—for example, an hypodermic injection, or any interference with the blood-supply of the part, whether this be the result of injury to a main artery or of prolonged maintenance of one position, when the local ischæmia thus produced—for example, in the buttock—may determine gangrene. In the latter situation direct infection from the bowel cannot be excluded, and this was probably the source in the ischio-rectal case referred to above. Neither of these factors could be established in the case reported. The only injection given into the right arm was an attempt soon after the operation to introduce strophanthin into the median basilic vein immediately below the level of the elbow-joint, some 3 inches distal to the lower margin of the gangrenous area. Examination both before and after death revealed no sign of injury to the arm, and certainly there was no gross abrasion of skin. There can be little doubt that the infection originated in the alimentary tract, though the actual portal of entry into the blood-stream remains obscure. It is possible that the organisms were present in the stomach at the time of operation, when the vessels opening on the cut surfaces of the gastric wall would offer a channel; on the other hand, infection may have occurred through some minute area of the wall of the bowel partly devitalised by handling during the operation.

I am indebted to Prof. Archibald Young, to whose wards the patient was admitted, for permission to publish this case.

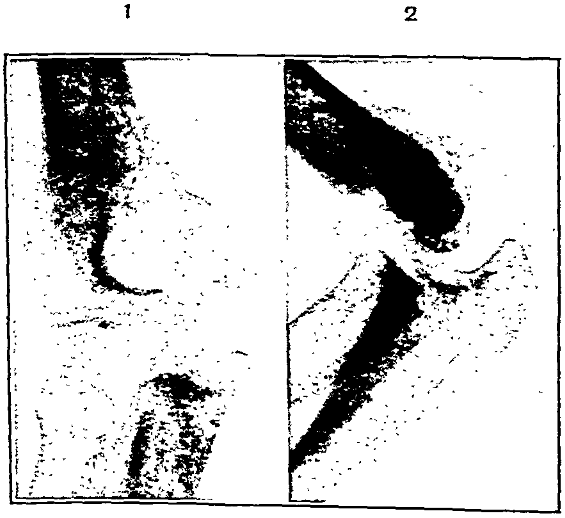
Clinical and Laboratory Notes.

INJURIES ABOUT THE ELBOW-JOINT.

By V. F. Soothill, M.D. Camb., D.P.H.,
ASSISTANT MEDICAL OFFICER OF HEALTH, ILFORD URBAN DISTRICT COUNCIL.

This is a plea for the more frequent use of X rays in the above class of injury. The following cases, illustrating the necessity, have attended the Ilford School Clinic in a little over a year:—

Case 1.—A. B., aged 8. This child fell and injured her left elbow and was seen by a medical man who was of opinion that there was no fracture. About three days later she attended the school clinic and the swelling aroused suspicion of a fracture, which was confirmed by X rays. She was sent by her doctor to hospital for treatment. The plates illustrating this fracture (Figs. 1 and 2) were kindly supplied from Great Ormond-street Hospital. The radiologist's report is, "Supracondylar fracture—comminuted. Slight inward and backward tilt of main fragment."



X ray illustrations showing fracture of elbow-joint (Case 1).

Case 2.—C. D., aged 7. The history of this case was given as follows. The boy fell on Jan. 16th, 1924, and injured his right elbow. He received treatment from a medical man, who said that the child need not attend again. A week later, dissatisfied with the condition of the boy's arm, the parent brought him to the school clinic. The alkali reserve also remains low for several days unless alkalis are administered.

Technique.

The technique which we employed may be divided into the following stages.

1. *Preparation Before Operation.*—For this at least a week appears to be necessary, during which hyperglycæmia and acidosis are removed and the patient is brought into nitrogenous equilibrium by appropriate diet and insulin dosage which naturally varies in each case. We did not attempt to fill the liver with glycogen as advocated by Joslin [5] and Barborka.[6] No food was given on the day of operation, half an hour before which 10 units of insulin were given.

2. *During Operation.*—Ether was invariably employed as an anæsthetic and was administered by the open method. Blood was removed simultaneously from the radial artery and median basilic vein at intervals of 20 minutes. Half an hour after the induction of anæsthesia insulin was given in amounts varying with the nature of the case.

3. *After Operation.*—This appears to be the most critical period. The patient was put on a milk diet, and the dosage of insulin governed by the magnitude of the post-operative hyperglycæmia. In post-operative infection either in the wound or arising from pulmonary conditions the reduction of hyperglycæmia presented great difficulty. A low post-operative alkali reserve may be effectively removed by alkalis as in Case 1.

The method used for the determination of glucose in the blood was the one described by Folin and Wu.[7] The carbon dioxide combining power of the blood was estimated by Van Slyke's method.[8] Diets used are in accordance with a simple scheme devised by one of us.[9] Operations were performed by Mr. G. C. E. Simpson and Dr. Leith Murray. Ether was administered by the open method preceded by the usual hypodermics.

Summary.

Ether anæsthesia in the diabetic produces a more severe hyperglycæmia and a greater fall in the alkali reserve than in a non-diabetic. They may be controlled by the pre-, intra-, and post-operative use of insulin. In spite of the administration of insulin the post-operative complication of sepsis appears to maintain both hyperglycæmia and a low alkali reserve; the latter may be restored by alkali therapy.

A CASE OF METASTATIC GAS GANGRENE

IN CIVIL PRACTICE.

BY J. R. LEARMONTH, M.B., CH.B. GLASG.,
EXTRA DISPENSARY SURGEON, WESTERN INFIRMARY, GLASGOW.*

THE following case presents a clinical picture so rare as to merit publication.

C. W., a coalman, aged 35, was admitted to the Western Infirmary, Glasgow, on March 21st, 1924. He stated that he had swung himself up on his lorry while it was in motion, whereupon he was seized immediately with epigastric pain so severe that he fell upon the pavement, where he remained until the arrival of the ambulance which brought him to the infirmary. On admission the temperature (rectal) was 99·2° F., the pulse 118, and the respirations 24. The whole abdomen was board-like in its rigidity and exquisitely tender. The patient was in great agony and collapsed. There was no vomiting. It was found that for two years he had suffered at intervals from epigastric pain, which occurred shortly after meals; he had rarely vomited. The gastric symptoms had never been so severe as to force him to consult a doctor. A slight degree of constipation had been present for the same period.

A diagnosis of perforation of a gastric ulcer was made, and without delay I opened the abdomen through the upper part of the right rectus muscle. The peritoneal cavity contained a considerable quantity of turbid, straw-coloured fluid, which was removed with gauze sponges as completely as possible. Examination showed that the lesser curvature of the stomach, rather towards its pyloric end, was occupied by a large saddle-shaped ulcer. Attached to the peritoneum over the anterior half of this ulcer was a mass of partially organised fibrin about 2 inches in diameter, and in form like the top of a mushroom turned upside down. More recent adhesions bound this mass to the anterior edge and under surface of the left lobe of the liver. Tunnelling through its middle was a perforation which admitted the tip of the little finger. Invagination of the perforated ulcer was impossible owing to the presence of the bulky mass of fibrin; temporary drainage of the peritoneal cavity seemed insufficient in view of the length of the perforating passage and the hard unyielding character of its walls, so that primary V-shaped resection of the whole ulcerating area was decided upon as the only hopeful line of treatment. This was performed as rapidly as possible, silk being used for the outer Lembert suture and catgut for the inner suture. The incision was closed in layers without drainage, and a tube containing a gauze wick was placed in the recto-vesical pouch through a separate median suprapubic stab wound.

At the close of the operation the condition of the patient was very grave. On his return to the ward a pint of saline solution was administered by the rectum, and strophanthin gr. 1/250 was injected hypodermically; rectal salines (10 oz.) and strophanthin, gr. 1/250, were ordered to be given every four hours. On the following day the patient was still very ill—temperature 101·8° F., pulse 156, respirations 36. On the second morning after operation, however, his condition was markedly improved. The temperature was 99·2°, the pulse 112; and the respirations 28. The dose of strophanthin was reduced to gr. 1/250 every six hours. The improvement was well maintained throughout the day, but about midnight he complained of pain in his right upper arm, and the pulse-rate rose to 120. Examination showed a diffuse reddening of the outer wall of the right axilla, to which a wet dressing was applied. By the morning of the third day the temperature had risen to 102°, the pulse to 140, the respirations to 32, and he was slightly jaundiced. His general condition was obviously hopeless. Examination of the right arm revealed a diffuse swelling extending along the inner aspect of the arm from about 3 inches above the level of the elbow-joint to the apex of the axilla. The skin over this area was a dusky purple colour and insensitive and crepitation could be elicited over its whole extent. Two parallel longitudinal incisions were made throughout the whole length of the swelling; these allowed the escape of gas under considerable tension. The muscles on the inner aspect of the arm were pale, quite necrotic, and riddled with gas bubbles. The wounds were swabbed out with peroxide of hydrogen, and a wet dressing was applied.† The patient died at 1 P.M., exactly 72 hours after the perforation of his ulcer; he had exhibited to a marked degree the retention of mental faculties found in this type of infection.

Bacteriological Report.

A portion of the necrotic material from the arm, obtained during life, was examined in the clinical laboratory of the Western Infirmary by Dr. E. M. Dunlop, who reported:—

* During the tenure of a grant from the Medical Research Council.

† Messrs. Burroughs, Wellcome and Co. inform me that they have still in stock antitoxic serum for administration in cases of gas gangrene due to *B. welchii*. As this serum was prepared some years ago they naturally do not guarantee its potency, but it might prove useful in such an emergency as described above.

The following Regulations will apply to all candidates who pass the Preliminary Examination in General Education on or after Jan. 1st, 1923.

1. Candidates for the Licence in Dental Surgery of the Royal College of Surgeons of England are required to pass one of the Examinations in General Education recognised by the Conjoint Examining Board in England, and the Pre-Medical Examination in Chemistry and Physics conducted by that Board or one of the examinations recognised in lieu thereof, before they commence the curriculum of professional study for the Licence extending over four years.

2. Candidates who produce evidence of having been registered by the General Medical Council as Medical or Dental Students on or after Jan. 1st, 1923, will be considered to have passed the required Preliminary Examination in General Education and the Pre-Medical Examination.

3. Candidates who hold the degree of D.M.D. Harvard, D.D.S. Pennsylvania, D.D.S. Michigan, D.D.S. Illinois, D.D.S. St. Louis, Missouri, D.D.S. Northwestern University, Chicago, D.D.S. Minnesota, D.D.S. Sydney, or the Licence of the Dental Board of Victoria, Australia, are not required to pass these *Examinations.*

First Professional Examination.—1. The First Professional Examination consists of Part I. Dental Mechanics, Part II. Dental Metallurgy, and Part III. Section (*a*) General Anatomy and Physiology, Section (*b*) Dental Anatomy and Physiology, and is held in January or February, April, and September or October in each year.

2. Candidates may present themselves for the several Parts of the First Professional Examination together or separately, but before admission to any part of the Examination they must produce evidence of having passed the required Preliminary Examination in General Education and the required Pre-Medical Examination or a certificate of having been registered as a Medical or Dental Student by the General Medical Council.

Part I. *Dental Mechanics.*—3. This Examination is a practical one, conducted in the Mechanical Laboratory of one of the Dental Hospitals in London.

4. Candidates must give 21 days' notice in writing of their intention to present themselves for the Examination, and at the same time forward certificates :—

(1) Of having been engaged during a period of not less than two years in acquiring a practical familiarity with the details of Dental Mechanics. One year at least of this study must be taken in the Mechanical Department of a recognised Dental Hospital where the arrangements for teaching Dental Mechanics are satisfactory to the Board of Examiners in Dental Surgery. Part or the whole of the rest of the course may be taken as a pupil with a competent dentist provided that time spent as a private pupil shall be at least twice the time required for the corresponding instruction[*] taken at a Dental School.

(2) Of having attended at a recognised Dental Hospital and School: (*a*) A course of lectures on Dental Mechanics; (*b*) a course of Practical Dental Mechanics, including the manufacture and adjustment of 6 dentures and 6 crowns.

6. Any candidate referred at this Examination who does not hold a registrable Dental Qualification will be required, before admission to re-examination, to produce a certificate of having received three months further instruction under the conditions specified in Certificate (1) paragraph 4.

Part II. *Dental Metallurgy.*—7. This Examination is conducted by written paper.

8. Candidates must give 21 days' notice in writing of their intention to present themselves for the Examination, and at the same time forward a certificate :—Of having attended at a recognised Dental Hospital and School: (*a*) A course of lectures on Dental Metallurgy; (*b*) a course of Practical Dental Metallurgy.

9. Any candidate referred at this Examination who does not hold a registrable Dental Qualification will be required, before admission to re-examination, to produce a certificate of having received, subsequently to the date of reference, not less than three months' instruction in Dental Metallurgy in a recognised Dental School.

Part III. (*a*) *General Anatomy and Physiology*, (*b*) *Dental Anatomy and Physiology.*—10. This Examination is partly written and partly oral.

11. Candidates may enter for Section (*a*) only or for Sections (*a*) and (*b*) together on producing the required certificates, but they will not be allowed to proceed with Section (*b*) until they have passed in Section (*a*). In the case of a candidate who enters for both Sections and fails in Section (*a*) the fee paid for admission to Section (*b*) will not be forfeited, but will be credited to the candidate on readmission to examination in that Section. Candidates who enter for both Sections together may pass in Section (*a*) although failing to pass in Section (*b*).

12. Candidates must give 21 days' notice in writing of their intention to present themselves for the whole or for one Section of this examination and at the same time forward certificates :—

(1) For Part III. (*a*). Of having attended at a recognised Medical School: (*a*) Courses of instruction in Anatomy, including special demonstrations on prepared dissections during three terms; (*b*) a course of dissections to include, if possible, the head and neck, during one term; (*c*) courses of instruction in Physiology including General Biology, Biochemistry, and Biophysics, during three terms; (*d*) a course of instruction in Histology.

(2) For Part III. (*b*). Of having attended at a recognised Dental School: (*a*) A course of instruction in Dental Anatomy and Physiology; (*b*) a separate course of instruction in Dental Histology, including the preparation of Microscopical Sections.

13. A candidate referred at this examination who does not hold a registrable Dental Qualification will be required, before readmission to Section (*a*), to produce a certificate of three months' additional study of Anatomy and Physiology at a recognised Medical School, and will be required before readmission to Section (*b*) to produce a certificate of three months' additional study of Dental Anatomy and Physiology at a recognised Dental School.

14. *Exemptions.*—Candidates who have passed Section I. of the First Professional Examination of the Conjoint Examining Board in England, or who produce evidence of having passed the Examination in Anatomy and Physiology for a degree, or other qualification, in Medicine or Surgery, registrable under the Medical Act of 1886, or for the degree of M.B. or M.D. of a Foreign or Colonial University recognised by the Conjoint Examining Board in England, are not required to pass Section (*a*).

Second Professional Examination.—1. The Second Professional Examination is held in February, May or June, and November in each year, and consists of: Part I., General Surgery and Pathology; Part II., Dental Surgery and Pathology, and Practical Dental Surgery.

2. Candidates who have passed the First Professional Examination at least six months[†] previously may present themselves for Part I. only on producing the certificates mentioned in paragraph 6 of this section, or they may enter for the whole Examination at one time on producing the certificates mentioned in paragraphs 6 and 10 of this section.

3. Candidates must pass in Part I. before proceeding to Part II.

4. Candidates who enter for the whole Examination at one time may pass in Part I. although failing to pass in Part II.; but if they fail to pass in Part I. they will not be allowed to proceed with the Practical and Oral Examinations in Part II. In such cases the fee paid for admission to Part II. will not be forfeited, but will be held over until such time as the candidate is readmitted to examination in that Part.

Part I. *General Surgery and Pathology.*—5. This Examination is partly written and partly oral.

---

[*] This instruction may be taken prior to the date of passing the Examination in General Education and the Pre-Medical Examination, but will not be counted as part of the required four years of professional study unless taken after passing the Pre-Medical Examination.

[†] The interval of six months is not required in the case of a colonial or foreign dentist.

nature of the swelling suggested a fracture, which was confirmed by X rays. He was transferred to hospital for treatment. He still has considerable deformity and limitation of extension. The radiologist's report is, "Separated epiphysis, lower end of humerus, with backward displacement."

CASE 3.—E. F., aged 13. Fell and injured his left elbow on March 17th, 1924. He attended the school clinic next day. There was some swelling and, as I could not exclude fracture, he was X rayed. There was no fracture. I saw him again four days later and the swelling presented the typical appearance of fluid in the joint. I include this case for comparison with Case 4.

CASE 4.—G. H., aged 8. This boy fell and injured his left elbow on March 21st, 1924. He attended the school clinic next morning (Saturday). There was a little swelling, but I could find no evidence of fracture, and considered it a case of synovitis like Case 3. An X ray was unobtainable that day, so the arm was bandaged to the chest in a flexed position, and the mother instructed to return with him on Monday. On the Monday the extent of the swelling suggested a fracture, which was confirmed by X rays, and the boy was transferred to hospital for treatment. The radiologist's report was, "Separated epiphysis, lower end of humerus. No displacement."

Of these four consecutive cases of injury to the elbow, three were fractures and not one of them was diagnosed when first seen. Probably they were not diagnosable except by skiagram, as Cases 1 and 2 had both been seen by medical practitioners who had not informed the parents of any fracture; and I could not tell the difference, on first seeing them, between Cases 3 and 4, although one had a fracture and the other had not. The necessity for discovering definitely the presence of fracture, even if "only" a separated epiphysis, is shown by the poor result in Case 2. If an X ray is not obtainable immediately, the case should be seen again, and if there be any suspicion of fracture a skiagram should be obtained even at the cost of some trouble. I have found that a generalised swelling, not confined to the synovial membrane and still seen on and after the third day, strongly suggests the advisability of obtaining a skiagram.

I am indebted to Dr. A. H. G. Burton, medical officer of health of Ilford, for permission to publish these cases.

VAGINAL HÆMORRHAGE FROM PERFORATING ENDOTHELIOMA.

BY W. B. COSENS, M.R.C.S. ENG.,
HON. SURGEON, DORSET COUNTY HOSPITAL.

THE rarity of this condition and the youth of the patient justify recording this case of alarming vaginal hæmorrhage.

Miss ——, aged 20, had been apparently in excellent health, the last period having ended 14 days previously. At 7 A.M. she was seized with severe vaginal hæmorrhage. Dr. T. B. Broadway, of Dorchester, found, under an anæsthetic, a large tumour pressing down the anterior wall of the vagina, but was unable to palpate the cervix. There was a well-formed hymen.

On admission to hospital the hæmorrhage continued in spite of gauze-packing. A hard, but slightly resilient, mass was felt resembling in contour a seven months' pregnancy. The abdomen was opened and a tumour was shelled out of the retroperitoneal space between the bladder and vagina; it was adherent to the anterior vaginal wall. The tumour weighed 1 lb. 2 oz. There was an abscess between the anterior fornix and the adherent part of the tumour, the hæmorrhage being due to perforation of the vaginal arteries in the site of the abscess cavity. Owing to the total disorganisation of the upper portion of the vagina, and its septic condition, the uterus was removed.

Pathological Report.—"An encapsulated, solid, and capillary fibro-hæmangio-endothelioma of vaginal wall."

The patient is now in excellent health. It is a question of doubt if she should receive X ray vaginal treatment, the ovaries being left and apparently healthy. The specimen is to be shown by Dr. Russell Andrews at the next meeting of the Section of Obstetrics and Gynæcology, Royal Society of Medicine.

STUDENTS' GUIDE—SESSION 1924-25.

DENTAL SURGERY.

APPEARANCE on the Medical Register entitles a practitioner to practise as a dentist, although he cannot register as such without degree or licence in dentistry; but few dental appointments at general or special hospitals or dispensaries are available save to those with a special diploma.

In THE LANCET of August 30th (p. 477) we outlined the constitution of the Dental Board of the United Kingdom, and the regulations in regard to the registration of dental students. In the following syllabus the respective requirements of the various examining bodies in dentistry are set forth, together with the facilities for dental study offered by certain other institutions.

THE EXAMINING BODIES IN DENTISTRY.

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND grants a diploma in Dental Surgery under the following regulations, which apply to all candidates who have passed the required Preliminary Examination in General Education before Jan. 1st, 1923.

Candidates are required to pass three examinations: the Preliminary Science Examination, the First Professional Examination, and the Second Professional Examination. 1. Preliminary Science Examination.—This is identical with Part I. of the First Examination of the Examining Board in England. Candidates who commenced professional study on or after Oct. 1st, 1913, must pass the Preliminary Science Examination before commencing the courses required for the Second Professional Examination. 2. The First Professional Examination.—The candidate must produce evidence of instruction in Dental Metallurgy and Practical Dental Mechanics. The Examination consists of Part I. (Mechanical Dentistry), Part II. (Dental Metallurgy), the examination in Dental Metallurgy being by written paper, and Part III. (*a*) General Anatomy and Physiology, (*b*) Dental Anatomy and Physiology conducted by papers and vivâ voce examination. The parts may be taken together or separately. 3. The Second Professional Examination.—This is divided into two parts: (*a*) the General, (*b*) the Dental. The General part must be passed before the Dental portion. The instruction is obtained partly at a General Hospital and partly at a Dental Hospital. The Second Professional Examination consists of: Part I., General Surgery and Pathology; Part II., Dental Surgery and Pathology, and Practical Dental Surgery. There is a written and vivâ voce examination in each part and a practical examination as well in Part II. Exemption from the Preliminary Science Examination is granted to candidates who have passed an Examination in Chemistry and Physics for a degree in Medicine at a University in the United Kingdom, in India, or in a British colony. Exemption from Examination in Anatomy and Physiology is granted to candidates who have passed the Second Examination of the Examining Board in England or the corresponding Examination for any degree or qualification in Medicine or Surgery registrable under the Medical Act of 1886. Exemption from Examination in General Surgery and Pathology is granted to candidates who have passed the Examination in Surgery of the Examining Board in England or the corresponding Examinations of the Colleges and University above mentioned. The fee for the diploma is 20 guineas, and is payable as follows: Preliminary Science Examination, for each admission to Part I., £3 3*s.*; Part II., £2 2*s.* First Professional Examination, for each admission to Part I., £4 4*s.*; Part II., £1 1*s.*; Part III. (*a*) £2 2*s.*; (*b*) £2 2*s.*; Second Professional Examination, for each admission to Part I., £2 2*s.*; Part II., £4 4*s.*

will be clinical and practical as well as written and oral. Candidates will be expected to show a high degree of knowledge and skill.

Royal Faculty of Physicians and Surgeons of Glasgow.—The regulations as to certificates, curriculum, number, and subjects of examinations, fees, &c., are in effect similar to those of the Royal College of Surgeons of Edinburgh, but embrace Dental Bacteriology. Candidates can enter for the First Examination in three divisions, the first embracing Physics and Chemistry, the second Dental Metallurgy and Dental Mechanics, and the third Anatomy and Physiology. The examination in Dental Mechanics is practical; and there is at the Final Examination an examination in Practical Dentistry conducted in a dental hospital. Copies of regulations, &c., to be obtained from Mr. Walter Hurst, Registrar, Faculty Hall, 242, St. Vincent-street, Glasgow. Candidates applying for Regulations should state date of commencement of curriculum.

Royal College of Surgeons in Ireland.—Candidates for the Licence in Dental Surgery, aged at least 21, pass two professional examinations. Before the First Examination the candidate must produce evidence of having attended courses in Theoretical and Practical Chemistry, including Metallurgy and Physics, at a recognised institution; of having been registered as a medical or dental student by the General Medical Council; and of having attended courses of instruction in the following subjects at a recognised school of medicine: (*a*) Anatomy Lectures; (*b*) Dissections with Demonstrations; (*c*) Physiology, including Dental Physiology; (*d*) Practical Physiology and Histology, including Dental Physiology and Histology, Human and Comparative. Before the Final Dental Examination the candidate must have been engaged during a period of two years in acquiring a practical familiarity with the details of Mechanical Dentistry under the instruction of a registered dentist, or under the direction of the superintendent of the Mechanical Department of a recognised Dental Hospital, and have attended, at institutions recognised by the College for the purpose, the following courses of instruction: (*a*) Dental Surgery and Pathology, Orthodontia, and the Materia Medica and Therapeutics applicable to Dental Surgery. Lectures. Two courses. (*b*) Dental Mechanics. Lectures. Two courses. (*c*) Dental Anatomy. Lectures. One course. (*d*) The practice of a Dental Hospital, or of the Dental Department of a General Hospital. Two years. He must also have attended Clinical instruction at a recognised General Hospital during the ordinary teaching sessions (nine months), and have been engaged during four years in the acquirement of professional knowledge subsequently to the date of registration as a medical or dental student. One year's bona-fide apprenticeship with a registered dental practitioner, after being registered as a medical or dental student, may be counted as one of the four years of professional study. In the First Dental Examination candidates will be examined in (A) Physics and Chemistry, including Practical Chemistry and Metallurgy. (B) Anatomy, Physiology, and Histology—General and Dental. All the subjects may be passed at the same time, or they may be passed in two groups (A and B).

In the Final Dental Examination candidates will be examined in General Pathology, Medicine, and Surgery; Dental Surgery, and Dental Pathology, with the Materia Medica and Therapeutics applicable to Dental Surgery; Dental Mechanics and Metallurgy; Orthodontia. Candidates must pass in all the subjects at one examination. The total fee for the Diploma in Dental Surgery is 20 guineas.

University of Birmingham.—The teaching of Dentistry is undertaken by the University acting in association with the Birmingham Dental Hospital and the Birmingham Clinical Board. The instruction at the Dental Hospital is carried out under the direction of the University Dental Clinical Board, so that students may fully qualify themselves for the Dental Diploma (L.D.S.) of this and other universities and licensing bodies. There is a special and well-equipped Dental Museum: The "John Humphreys Odontological Museum." An Entrance Exhibition, value £37 10s., is awarded annually at the commencement of the winter session. The following are the regulations for Degrees in Dentistry:—

1. The degrees conferred by the University are those of Bachelor and Master of Dental Surgery (B.D.S. and M.D.S.). 2. All candidates for these degrees must pass the same Matriculation Examination as that required from candidates for Medical Degrees. 3. The degree of Bachelor of Dental Surgery is not conferred upon any candidate who has not obtained a Licence in Dental Surgery. The candidate is not eligible for the degree until a period of 12 months has elapsed from the passing of his examination for the Licence in Dental Surgery. Of this period at least six months must be spent in the dental department of a general hospital approved by the University. 4. *A*. In addition to the Licence in Dental Surgery the candidate must produce evidence that he has attended the courses required by medical students of the University in the following subjects and passed the Examinations held in the same for Medical and Surgical Degrees: (*a*) Elementary Biology and Organic Chemistry, (*b*) Anatomy and Practical Anatomy, and (*c*) Physiology and Practical Physiology. *B*. That he has passed the class examinations in: (*d*) One Special Course of Lectures on Medicine, (*e*) One Special Course of Lectures on Surgery, and (*f*) Pathology and Bacteriology. *C*. That he has attended courses and passed the class examinations in: (*g*) Dental Histology and Patho-Histology, (*h*) Comparative Dental Anatomy, and (*k*) Dental Surgery and Prosthetic Dentistry. *D*. That he has received instruction in the Clinical Examination of living cases at the dental department of a general hospital for a period of not less than six months. 5. The Final Examination will deal with the subjects in Classes *C* and *D*. 6. On the expiration of 12 months from the date of passing the Examination for the Degree of Bachelor of Dental Surgery, the candidate will be eligible for that of Master of Dental Surgery. 7. For this degree candidates will be required to submit a thesis containing original work, and investigations in some subject connected with Dentistry, which theses shall be submitted to examiners to be nominated by the Dental Advisory Board.

University of Bristol.—Candidates for the degree of Bachelor of Dental Surgery must be not less than 21 years of age and shall have pursued the courses prescribed by University regulations during not less than four years after passing the first examination in the subjects of Chemistry and Physics, of which three shall have been passed in the University. All candidates for the degree of B.D.S. are required to satisfy the examiners in the several subjects of four examinations. The First Examination: The subjects are Chemistry, Physics, and Biology, and the curriculum extends over one year.* The Third Examination: The subjects are Dental Mechanics, Dental Metallurgy, and Dental Materia Medica, and the candidate shall produce evidence of having served for three years an approved pupilage in Dental Mechanics.† The Second Examination: The subjects are Anatomy, Physiology, and Histology, Dental Anatomy, and Dental Histology. The Final Examination: The subjects are Medicine and Surgery, Dental Surgery (including Prosthetics), Operative Dental Surgery, and Dental Bacteriology. Degree of Master of Dental Surgery: Candidates shall be Bachelors of the University, shall present a Dissertation on some subject of Dental

---

* Candidates who have passed the Higher School Certificate approved by the Board of Education in these subjects will not be required to sit for the first examination for either the B.D.S. or the L.D.S., and will be regarded as having completed one year of study.

† This pupilage must be taken either in the University laboratories or those of some institution recognised for the purpose by the University.

6. Candidates must give 21 days' notice in writing of their intention to present themselves for this Examination, and at the same time forward certificates:—

(1) Of having attended at a recognised Medical School: (a) A course of instruction[‡] in Surgery during two terms; (b) a course of instruction in Medicine during two terms; (c) a course of instruction in General Pathology (including Bacteriology) during two terms. (2) Of having acted as Surgical Dresser in the Out-patient Department of a recognised Hospital for three months. (3) Of having attended, at a recognised Hospital or Hospitals, the practice of Medicine and Surgery, including clinical lectures, for 12 months. (4) Of being 21 years of age.

7. Any candidate referred at this Examination who does not hold a registrable Dental Qualification will be required, before admission to re-examination, to produce a certificate of such additional study during three months at a recognised Medical School and Hospital as the Teachers of the School may determine.

Exemptions.—8. Candidates who are Members of the College or who have passed the Examination in Surgery of the Conjoint Examining Board in England, or who produce evidence of having passed the Examination in Surgery for a Degree, or other Qualification in Medicine or Surgery registrable under the Medical Act of 1886, are not required to pass Part I. of the Second Professional Examination.

Part II. *Dental Surgery and Pathology.*—This Examination is partly written, partly oral, and partly practical. The oral examination is conducted by the use of preparations, casts, drawings, &c. At the practical examination candidates may be examined:—

(a) On the treatment of Dental Caries, on the preparation and treatment of teeth by filling with gold or other material, by inlaying or by crowning, and on other operations in Dental Surgery. (Candidates must provide their own instruments.) (b) On the treatment of abnormalities of position of the teeth of children. (c) On Clinical cases.

10. Candidates must give 21 days' notice in writing of their intention to present themselves for this Examination, and at the same time forward certificates:—

(1) Of having been engaged during four years in the acquirement of professional knowledge subsequently to the date of registration as a Medical or Dental Student, or of having passed the Pre-Medical Examination conducted or recognised by the Conjoint Examining Board in England. (2) Of having attended at a recognised Dental Hospital and School: (a) A course of Dental Surgery and Pathology; (b) a separate course of Practical Dental Surgery; (c) a course of Dental Bacteriology; (d) a course of Dental Materia Medica; (e) a course of practical instruction in the administration of such Anæsthetics as are in common use in Dental Surgery. (3) Of having attended at a recognised Dental Hospital and School, or in the Dental Department of a recognised General Hospital, the practice of Dental Surgery during two years.

11. Any candidate referred at this Examination who does not hold a registrable Dental Qualification will be required before admission to re-examination to produce a certificate of three months' additional study at a recognised Dental Hospital.

Fees.—The fee for the Diploma in Dental Surgery is 20 Guineas.

Synopses of examinations and all further information can be obtained from the Secretary, Examination Hall, Queen-square, London, W.C. 1.

ROYAL COLLEGE OF SURGEONS, EDINBURGH.—Regulations giving a list of Preliminary Examinations recognised for obtaining the Licence in Dental Surgery, as well as of the subjects of the Professional Examinations, may be obtained from Mr. D. L. Eadie, Clerk to the Royal College of Surgeons, at 49, Lauriston-place, Edinburgh. Candidates must produce certificates of having, subsequently to the date of registration, been engaged for four years in professional studies and of three years' instruction in Mechanical Dentistry from a registered dental practitioner, except in the case of previously registered medical practitioners, when two years will be considered sufficient. Candidates must also have attended a course of instruction at a University or in an established school of medicine or in a provincial school specially recognised by the College as qualifying for the Diploma in Surgery. In addition they will be required to have attended in a recognised dental hospital, or with teachers recognised by the College, special courses of lectures and instruction in Anatomy and Physiology (Human and Comparative), Surgery, Pathology, Materia Medica, Dental Histology, and Practical Dental Mechanics and Metallurgy; two years' attendance at a dental hospital or the dental department of a general hospital recognised by the College. Practical instruction in Mechanical Dentistry from a registered Dentist, or in the Mechanical Department of a recognised Dental Hospital and School, for three years. Candidates who have passed the First and Second Examinations for the Triple Qualification will be exempt from the First Dental Examination, and will have the advantage of being admissible either to the Final Dental Examination or to the subsequent Examination for the Triple Qualification, or to both. But the First Dental Examination will not be held as equivalent to the First and Second Triple Examinations, and will admit to the Final Dental Examination only. Candidates who are Licentiates of this College or who may be registered medical practitioners will be required to produce certificates of attendance on the special subjects only and will be examined in these only for the dental diploma. First Professional Examination: The candidate must have attended the required courses. The examination embraces (1) Chemistry and Physics; and (2) Anatomy and Physiology. The fee is £5 5s. for the complete examination, and £3 3s. is payable for each division. In all cases of rejected candidates the fee for re-entry is £3 3s. Second Examination: The candidate must have attended the remaining courses of the curriculum, must produce certificates showing that he is 21 years of age, and must pay a fee of £10 10s., for re-entry £5 5s. The examination embraces (1) Surgery and Medicine; and (2) the special subjects of Dental Anatomy and Physiology, Dental Surgery and Pathology, Dental Materia Medica, Dental Mechanics and Dental Metallurgy, with a practical as well as the written and oral examinations in the subjects of Dental and Oral Surgery, Pathology, and Mechanics. The candidate will be tested in the Treatment of Dental Diseases, in Operative Dentistry, the Administration of Anæsthetics, Orthodontics, and in Prosthetic and Mechanical Dentistry. Candidates who claim exemption from the First Dental Examination on the ground of having passed the First and Second Triple Qualification Examinations or other recognised examinations will, before being admitted to the Second Dental Examination, be required to pay the total fee of £15 15s. payable for the dental diploma. Candidates applying for copies of Regulations should state date of registration as a dental student. Fees and schedules must be lodged with the Clerk not later than one week before the examination.

Separate Regulations are issued for candidates registered as Dental Students after Jan. 1st, 1923, for whom there is a much more extended course.

Higher Dental Diploma.—The College grants a Higher Dental Diploma which is registrable in the Dentists Register as an additional qualification. Every candidate for the Higher Dental Diploma shall produce evidence that he has been engaged in the study or practice of his profession as a Registered Dentist for at least one year subsequent to his having obtained the Licence in Dental Surgery of the College, or a Licence or Qualification in Dental Surgery specially recognised by the College. Particulars as to the examinations can be obtained from Mr. D. L. Eadie, Clerk to the Royal College of Surgeons, 49, Lauriston-place, Edinburgh. The fee payable by Licentiates of the College is £15 15s. For all other candidates £21. A fee of £10 10s. is retained for examination expenses in the case of referred candidates.

The examination embraces the following branches of Dental Science and practice: Dental Surgery, Anatomy, Pathology and Bacteriology, Prosthesis, Anæsthesia, and Dental Radiology. The examination will be clinical and practical as well as written and oral. Candidates will be expected to show a high degree of knowledge and skill.

[‡] These courses of instruction must be attended after the completion of the courses in Anatomy and Physiology.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—The regulations as to certificates, curriculum, number, and subjects of examinations, fees, &c., are in effect similar to those of the Royal College of Surgeons of Edinburgh, but embrace Dental Bacteriology. Candidates can enter for the First Examination in three divisions, the first embracing Physics and Chemistry, the second Dental Metallurgy and Dental Mechanics, and the third Anatomy and Physiology. The examination in Dental Mechanics is practical; and there is at the Final Examination an examination in Practical Dentistry conducted in a dental hospital. Copies of regulations, &c., to be obtained from Mr. Walter Hurst, Registrar, Faculty Hall, 242, St. Vincent-street, Glasgow. Candidates applying for Regulations should state date of commencement of curriculum.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—Candidates for the Licence in Dental Surgery, aged at least 21, pass two professional examinations. Before the First Examination the candidate must produce evidence of having attended courses in Theoretical and Practical Chemistry, including Metallurgy and Physics, at a recognised institution; of having been registered as a medical or dental student by the General Medical Council; and of having attended courses of instruction in the following subjects at a recognised school of medicine: (a) Anatomy Lectures; (b) Dissections with Demonstrations; (c) Physiology, including Dental Physiology; (d) Practical Physiology and Histology, including Dental Physiology and Histology, Human and Comparative. Before the Final Dental Examination the candidate must have been engaged during a period of two years in acquiring a practical familiarity with the details of Mechanical Dentistry under the instruction of a registered dentist, or under the direction of the superintendent of the Mechanical Department of a recognised Dental Hospital, and have attended, at institutions recognised by the College for the purpose, the following courses of instruction: (a) Dental Surgery and Pathology, Orthodontia, and the Materia Medica and Therapeutics applicable to Dental Surgery. Lectures. Two courses. (b) Dental Mechanics. Lectures. Two courses. (c) Dental Anatomy. Lectures. One course. (d) The practice of a Dental Hospital, or of the Dental Department of a General Hospital. Two years. He must also have attended Clinical instruction at a recognised General Hospital during the ordinary teaching sessions (nine months), and have been engaged during four years in the acquirement of professional knowledge subsequently to the date of registration as a medical or dental student. One year's bona-fide apprenticeship with a registered dental practitioner, after being registered as a medical or dental student, may be counted as one of the four years of professional study. In the First Dental Examination candidates will be examined in (A) Physics and Chemistry, including Practical Chemistry and Metallurgy. (B) Anatomy, Physiology, and Histology—General and Dental. All the subjects may be passed at the same time, or they may be passed in two groups (A and B).

In the Final Dental Examination candidates will be examined in General Pathology, Medicine, and Surgery; Dental Surgery, and Dental Pathology, with the Materia Medica and Therapeutics applicable to Dental Surgery; Dental Mechanics and Metallurgy; Orthodontia. Candidates must pass in all the subjects at one examination. The total fee for the Diploma in Dental Surgery is 20 guineas.

UNIVERSITY OF BIRMINGHAM.—The teaching of Dentistry is undertaken by the University acting in association with the Birmingham Dental Hospital and the Birmingham Clinical Board. The instruction at the Dental Hospital is carried out under the direction of the University Dental Clinical Board, so that students may fully qualify themselves for the Dental Diploma (L.D.S.) of this and other universities and licensing bodies. There is a special and well-equipped Dental Museum: The "John Humphreys Odontological Museum." An Entrance Exhibition, value £37 10s., is awarded annually at the commencement of the winter session. The following are the regulations for Degrees in Dentistry:—

1. The degrees conferred by the University are those of Bachelor and Master of Dental Surgery (B.D.S. and M.D.S.). 2. All candidates for these degrees must pass the same Matriculation Examination as that required from candidates for Medical Degrees. 3. The degree of Bachelor of Dental Surgery is not conferred upon any candidate who has not obtained a Licence in Dental Surgery. The candidate is not eligible for the degree until a period of 12 months has elapsed from the passing of his examination for the Licence in Dental Surgery. Of this period at least six months must be spent in the dental department of a general hospital approved by the University. 4. *A*. In addition to the Licence in Dental Surgery the candidate must produce evidence that he has attended the courses required by medical students of the University in the following subjects and passed the Examinations held in the same for Medical and Surgical Degrees: (a) Elementary Biology and Organic Chemistry, (b) Anatomy and Practical Anatomy, and (c) Physiology and Practical Physiology. *B*. That he has passed the class examinations in: (d) One Special Course of Lectures on Medicine, (e) One Special Course of Lectures on Surgery, and (f) Pathology and Bacteriology. *C*. That he has attended courses and passed the class examinations in: (g) Dental Histology and Patho-Histology, (h) Comparative Dental Anatomy, and (k) Dental Surgery and Prosthetic Dentistry. *D*. That he has received instruction in the Clinical Examination of living cases at the dental department of a general hospital for a period of not less than six months. 5. The Final Examination will deal with the subjects in Classes *C* and *D*. 6. On the expiration of 12 months from the date of passing the Examination for the Degree of Bachelor of Dental Surgery, the candidate will be eligible for that of Master of Dental Surgery. 7. For this degree candidates will be required to submit a thesis containing original work, and investigations in some subject connected with Dentistry, which theses shall be submitted to examiners to be nominated by the Dental Advisory Board.

UNIVERSITY OF BRISTOL.—Candidates for the degree of Bachelor of Dental Surgery must be not less than 21 years of age and shall have pursued the courses prescribed by University regulations during not less than four years after passing the first examination in the subjects of Chemistry and Physics, of which three shall have been passed in the University. All candidates for the degree of B.D.S. are required to satisfy the examiners in the several subjects of four examinations. The First Examination: The subjects are Chemistry, Physics, and Biology, and the curriculum extends over one year.* The Third Examination: The subjects are Dental Mechanics, Dental Metallurgy, and Dental Materia Medica, and the candidate shall produce evidence of having served for three years an approved pupilage in Dental Mechanics.† The Second Examination: The subjects are Anatomy, Physiology, and Histology, Dental Anatomy, and Dental Histology. The Final Examination: The subjects are Medicine and Surgery, Dental Surgery (including Prosthetics), Operative Dental Surgery, and Dental Bacteriology. Degree of Master of Dental Surgery: Candidates shall be Bachelors of the University, shall present a Dissertation on some subject of Dental

---

* Candidates who have passed the Higher School Certificate approved by the Board of Education in these subjects will not be required to sit for the first examination for either the B.D.S. or the L.D.S., and will be regarded as having completed one year of study.

† This pupilage must be taken either in the University laboratories or those of some institution recognised for the purpose by the University.

Surgery to be approved by the Examiners, and pass an examination in Dental Surgery. Diploma in Dental Surgery: Candidates need not be undergraduates, but shall have passed an entrance examination satisfactory to the University before being admitted to any professional examination; the curriculum extends over four years from the date of passing a preliminary science examination in Chemistry and Physics. A three years' pupilage in Mechanical Dentistry is required[†] and four examinations must be passed, the subjects of which agree with those of the B.D.S. Medicine is not required for the Final Examination. Candidates who are already registered medical practitioners shall be further exempted from study and examination in Physics and Chemistry, Anatomy, Physiology and Histology, Medicine, and General Surgery.

UNIVERSITY OF DURHAM.—Every Dental student must, at the commencement of his studentship, be registered in the manner and under the conditions prescribed for Medical students.

First Examination for the Licence in Dental Surgery: This examination consists of two parts, which may be passed separately. Part 1, Biology, Organic Chemistry. Part 2, Theoretical Dental Mechanics, Dental Metallurgy (theoretical and practical). Second Examination: Anatomy, Physiology (including Biochemistry and Biophysics), Dental Anatomy and Dental Histology. Third Examination: Pathology and Bacteriology, Practical Dental Mechanics, Dental Materia Medica and Therapeutics. Final Examination: Medicine, Surgery, Dental Surgery and Pathology, Orthodontics, Operative Dental Surgery, and Dental Prosthetics, and Anæsthetics.

A candidate before presenting himself for examination is required to furnish certificates of instruction in the following subjects, attended after registration as a dental student at recognised Colleges or Schools: (*a*) Organic Chemistry; (*b*) Elementary Biology[‡]; (*c*) Human Anatomy, with dissections and demonstrations for three academic terms; (*d*) Physiology, including Biochemistry and Biophysics (with laboratory instruction, including practical Histology) for three academic terms; (*e*) General Pathology (including Bacteriology) for two academic terms; (*f*) Medicine for two academic terms; (*g*) Surgery for two academic terms; (*h*) the practice of a recognised General Hospital or Hospitals of not less than 80 beds, with certified instruction in Clinical Medicine and Clinical Surgery, for four academic terms. The certificates of teaching at General Hospitals must furnish evidence of the student having acted as Medical Clinical Clerk and Surgical Dresser, and of attendance in the Out-patient or Casualty Departments. A certificate of clinical instruction in Venereal Disease is required.

The candidate must have attended at a recognised Dental School courses of instruction in the following special subjects: (*a*) Dental Anatomy and Physiology, human and comparative. The course should comprise a minimum of 20 meetings of the class. (*b*) Practical Dental Histology and Morbid Histology. The course should comprise a minimum of 16 meetings of the class. (*c*) Dental Pathology and Surgery. The course should comprise a minimum of 20 meetings of the class. (*d*) Dental Materia Medica and Therapeutics. The course should comprise a minimum of 16 meetings of the class. (*e*) Dental Metallurgy (with practical work and demonstrations). The course should comprise a minimum of 20 meetings of the class. (*f*) Dental Mechanics (with practical work and demonstrations). The course should comprise a minimum of 20 meetings and 20 demonstrations. (*g*) A course of instruction in the use of Anæsthetics, general and local, employed in Dental Practice. (*h*) A course of instruction in Radiology as applied to Dentistry.

Note.—A candidate must produce a certificate of having administered general anæsthetics on at least ten occasions.

The candidate must have for at least 24 calendar months attended, during the ordinary academic terms, the practice of a recognised Dental Hospital or of the recognised Dental Department of a General Hospital, and have received for not less than 24 calendar months practical instruction in Dental Mechanics.

Note.—No portion of such practical instruction which is taken prior to the date of registration shall be reckoned as a portion of the four years of Professional Study required.

Instruction in Dental Mechanics should, if possible, be taken at a recognised Dental Hospital and School. If any part of such instruction be taken by the candidate as a pupil with a registered dentist the time required to be devoted to it shall be at least twice the time required for the corresponding instruction taken at a Dental Hospital and School.

Degree of Bachelor of Dental Surgery (*B.D.S.*).—(*a*) For students taking their complete course of instruction in the University. Such students must pass the same matriculation tests as medical students, and the same pre-registration examination in Inorganic Chemistry and Physics. After registration students must spend five years in the University, on attendance on such subjects as Senate, on the recommendation of the Board of the Faculty of Medicine, may from time to time determine. They must attend the practice of the Newcastle-upon-Tyne Dental Hospital for not less than two and a half years. Six months of this time must be devoted to the study of the higher branches of dental science. There are four examinations.

The subjects of the *first* examination are Biology and Organic Chemistry, of the same standard as for medical students; and Dental Mechanics and Metallurgy.

The subjects of the *second* examination are Anatomy, Physiology, Dental Anatomy and Histology.

The subjects of the *third* examination are Pathology and Bacteriology, Dental Materia Medica and Therapeutics, and Practical Dental Mechanics.

The subjects of the *final* examination are Medicine, Surgery, Dental Surgery and Pathology, and Orthodontia and Operative Dental Surgery. In this subject knowledge of a much higher standard, and more advanced practical work, will be required than for the Licence in Dental Surgery.

(*b*) For candidates possessing a Licence in Dental Surgery of a British University. Candidates must study for at least one year in the University. During such year they must (*a*) attend a course of instruction in Pathology and Bacteriology, and (*b*) spend at least six months in the Newcastle-upon-Tyne Dental Hospital in the study and practice of the higher branches of dental science. They must also pass the third and final examinations for the degree of Bachelor of Dental Surgery.

Degree of Master of Dental Surgery (*M.D.S.*).—Every candidate for this degree must be a Bachelor of Dental Surgery of the University of not less than two years' standing, and present an essay embodying original work and research in some subject connected with dentistry. They must also perform to the satisfaction of the examiners a piece of special dental work demanding a high degree of skill and experience.

The examinations are held concurrently with the medical examinations, and the fees payable by candidates for the Licence in Dental Surgery are as follows: First Examination, £2 10*s.*; Second Examination, £2 10*s.*; Third Examination, £3 10*s.*; Final Examination, £3 10*s.*; fee for Licence, £3; total, £15. For re-examination: First Examination, £1 10*s.*; Second Examination, £2; Third Examination, £2 (in one part only, £1); Fourth Examination, £2. The practical examinations in dentistry are conducted at the Newcastle Dental Hospital.

[†] See previous page.

[‡] A student who has diligently attended an approved course of Elementary Biology in a secondary school or other teaching institution recognised by the University may be admitted to a Professional Examination in Elementary Biology immediately after his registration as a dental student.

University of Leeds.—The degrees in Dental Surgery are Bachelor of Dental Surgery (B.Ch.D.) and Master of Dental Surgery (M.Ch.D.). All candidates for the degree of Bachelor of Dental Surgery shall be required to have passed the Matriculation Examination, to have pursued thereafter approved courses of study for not less than five academic years, two of such years at least having been passed in the University subsequently to the date of passing Parts I. and II. of the First Examination, and to have completed such period of pupilage or hospital attendance, or both, as may be prescribed by the regulations of the University. No candidate will be admitted to the degree who has not attained the age of 21 years on the day of graduation. The Diploma in Dental Surgery (L.D.S.) is awarded to successful candidates after attendance on approved courses extending over not less than four years. The curriculum for the Diploma now includes the study of Biology for the First Examination. The classes in the Department of Dentistry begin on Oct. 1st. The instruction in the Preliminary subjects of Chemistry, Physics, and Biology are given in the main buildings of the University. The classes in the other subjects and the systematic courses in Dental subjects are held in the School of Medicine of the University in Thoresby-place. The clinical instruction is given in the Dental Hospital at the Leeds General Infirmary. Applications for the prospectus should be made to the Academical Sub-Dean of the Faculty of Medicine.

University of Liverpool.—The University grants a Licence in Dental Surgery (L.D.S.) and degrees in Dental Surgery (B.D.S. and M.D.S.). The management of the curriculum (lectures, practical and clinical) is in the hands of the University Board of Dental Studies. The courses of systematic instruction are given in the main University buildings, and those in Dental Mechanics, Operative Dental Surgery, &c., are given in the University School Extension (opened 1922), adjoining the Dental Hospital, the laboratory of which is in charge of a skilled dental mechanic under the supervision of the Director of Dental Education. The clinical instruction is given in the Dental Hospital. Students can take the whole curriculum, including Dental Mechanics, at the University School of Dental Surgery. The times of the lectures at the University are arranged to meet the convenience of students, thus allowing the maximum time for attendance upon Dental Hospital practice. Fees: The fees for the complete courses, including Pupilage and Hospital Practice, are as follows: Degree of B.D.S., £250; M.D.S. (by research, £32; by examination, £27); L.D.S. (Liverpool), £198. Further information may be had from the Director of Dental Education, Prof. W. H. Gilmour.

In order to be admitted to the Bachelor's Degree in Dental Surgery a student must normally, after registration as an Internal Student, have—(1) Attended prescribed courses of study for five years at one or more Schools of the University. (2) Passed the following examinations:—(*a*) First Examination: *Part A*: (i.) Chemistry. (ii.) Physics, (iii.) Biology (Zoology and Botany); *Part B*: (iv.) Dental Metallurgy. Candidates may take Parts A and B separately. (*b*) Second Examination: *Part A* (i.) Anatomy, (ii.) Dental Anatomy, Dental Physiology, and Dental Histology; *Part B*: (iii.) Physiology; *Part C*: (iv.) Dental Mechanics. Candidates may take Part A separately but must take Parts B and C together. Third Examination: *Part A*: (i.) Elementary Bacteriology, (ii.) Clinical Chemistry, (iii.) General Pathology; *Part B*: (iv.) Dental Materia Medica, (v.) Dental Mechanics and Dental Prosthetics. Candidates may take Parts A and B separately. Students who have received not less than two years' instruction in Dental Mechanics previous to Nov. 30th, 1922, with a Dentist registered under the provisions of the Dentists Act (1921) and who have passed a recognised examination in preliminary education may, on application, be registered as students for the Licence under certain conditions.

University of London.—The curriculum for the degree of Bachelor of Dental Surgery covers five years from Matriculation. The Regulations for Internal and External Students may be obtained post-free on application to the Principal Officer, at the University.

University of Manchester.—In the University of Manchester the Dental Department forms an integral part of the Faculty of Medicine. This contains a series of laboratories, lecture rooms, and museums which will bear comparison with those of any other school in the kingdom, and the fullest opportunities for study are offered to students preparing for any of the professional examinations. Instruction adapted to the requirements of students preparing for the B.D.S. Degree and the Dental Diplomas of the University, the Royal College of Surgeons of England, and of other licensing bodies is given throughout the session both at the University and at the Dental Hospital of Manchester adjoining the University. The required general hospital practice is taken at the Manchester Royal Infirmary. Women students are admitted to the classes in the Dental Department, and for them common rooms are provided. The composition fee for candidates for the University degree of Bachelor of Dental Surgery is 93 guineas, payable in three equal yearly instalments. The composition fee for candidates for the University Diploma in Dentistry is 83 guineas, payable in three equal yearly instalments. The composition fee for candidates for the L.D.S. of England is 93 guineas, payable in three equal yearly instalments. Students who have already served their apprenticeship with a private practitioner, and who propose to complete the final portion of their attendance at the University and at an approved dental hospital, will be required to pay the composition fee in two equal instalments at the commencement of the first and second years of studentship. The composition fee does not include the hospital fees, the examination fees, nor the fee for the conferment of the degree or the diploma.

University of Sheffield.—*Degree of Bachelor of Dental Surgery.*—A candidate must have attained the age of 22 years on the day of graduation and have pursued the courses of study required by the University regulations during a period of not less than five and a half years subsequent to matriculation and the passing of the further examination in Chemistry and Physics, three of such years at least having been passed in the University, one at least being subsequent to the passing of the First Examination.

First Examination: The subject of the examination is Biology. Candidates must have attended a course of instruction for one year after matriculation and the passing of the further examination in Chemistry and Physics. Second Examination: The subjects of the examination are Anatomy, Physiology, Dental Anatomy, Physiology and Histology; Dental Mechanics, Dental Metallurgy. Final Examination: The subjects of the examination are: Part I., Pathology and Bacteriology; Part II., Medicine and Surgery, Dental Surgery, including Materia Medica and Therapeutics. Candidates for Part II. must have completed five and a half years of professional study.

Degree of Master of Dental Surgery.—Candidates must have passed the examination for the degree of B.D.S. at least one year previously and before admission to the examination must have held for not less than six months a dental appointment in a hospital affording full opportunity for the study of Dental Surgery. Candidates shall not be required to but may present a thesis embodying observations in some subject approved by the Faculty and a candidate whose thesis is of exceptional merit may be exempted from any part of the examination.

Diploma of Licentiate in Dental Surgery.—A candidate must have attained the age of 21 years on the day upon which he is to receive the diploma, and have pursued the courses of study required by the

Surgery to be approved by the Examiners, and pass an examination in Dental Surgery. Diploma in Dental Surgery: Candidates need not be undergraduates, but shall have passed an entrance examination satisfactory to the University before being admitted to any professional examination; the curriculum extends over four years from the date of passing a preliminary science examination in Chemistry and Physics. A three years' pupilage in Mechanical Dentistry is required† and four examinations must be passed, the subjects of which agree with those of the B.D.S. Medicine is not required for the Final Examination. Candidates who are already registered medical practitioners shall be further exempted from study and examination in Physics and Chemistry, Anatomy, Physiology and Histology, Medicine, and General Surgery.

University of Durham.—Every Dental student must, at the commencement of his studentship, be registered in the manner and under the conditions prescribed for Medical students.

First Examination for the Licence in Dental Surgery: This examination consists of two parts, which may be passed separately. Part 1, Biology, Organic Chemistry. Part 2, Theoretical Dental Mechanics, Dental Metallurgy (theoretical and practical). Second Examination: Anatomy, Physiology (including Biochemistry and Biophysics), Dental Anatomy and Dental Histology. Third Examination: Pathology and Bacteriology, Practical Dental Mechanics, Dental Materia Medica and Therapeutics. Final Examination: Medicine, Surgery, Dental Surgery and Pathology, Orthodontics, Operative Dental Surgery, and Dental Prosthetics, and Anæsthetics.

A candidate before presenting himself for examination is required to furnish certificates of instruction in the following subjects, attended after registration as a dental student at recognised Colleges or Schools: (*a*) Organic Chemistry; (*b*) Elementary Biology‡; (*c*) Human Anatomy, with dissections and demonstrations for three academic terms; (*d*) Physiology, including Biochemistry and Biophysics (with laboratory instruction, including practical Histology) for three academic terms; (*e*) General Pathology (including Bacteriology) for two academic terms; (*f*) Medicine for two academic terms; (*g*) Surgery for two academic terms; (*h*) the practice of a recognised General Hospital or Hospitals of not less than 80 beds, with certified instruction in Clinical Medicine and Clinical Surgery, for four academic terms. The certificates of teaching at General Hospitals must furnish evidence of the student having acted as Medical Clinical Clerk and Surgical Dresser, and of attendance in the Out-patient or Casualty Departments. A certificate of clinical instruction in Venereal Disease is required.

The candidate must have attended at a recognised Dental School courses of instruction in the following special subjects: (*a*) Dental Anatomy and Physiology, human and comparative. The course should comprise a minimum of 20 meetings of the class. (*b*) Practical Dental Histology and Morbid Histology. The course should comprise a minimum of 16 meetings of the class. (*c*) Dental Pathology and Surgery. The course should comprise a minimum of 20 meetings of the class. (*d*) Dental Materia Medica and Therapeutics. The course should comprise a minimum of 16 meetings of the class. (*e*) Dental Metallurgy (with practical work and demonstrations). The course should comprise a minimum of 20 meetings of the class. (*f*) Dental Mechanics (with practical work and demonstrations). The course should comprise a minimum of 20 meetings and 20 demonstrations. (*g*) A course of instruction in the use of Anæsthetics, general and local, employed in Dental Practice. (*h*) A course of instruction in Radiology as applied to Dentistry.

Note.—A candidate must produce a certificate of having administered general anæsthetics on at least ten occasions.

The candidate must have for at least 24 calendar months attended, during the ordinary academic terms, the practice of a recognised Dental Hospital or of the recognised Dental Department of a General Hospital, and have received for not less than 24 calendar months practical instruction in Dental Mechanics.

Note.—No portion of such practical instruction which is taken prior to the date of registration shall be reckoned as a portion of the four years of Professional Study required.

Instruction in Dental Mechanics should, if possible, be taken at a recognised Dental Hospital and School. If any part of such instruction be taken by the candidate as a pupil with a registered dentist the time required to be devoted to it shall be at least twice the time required for the corresponding instruction taken at a Dental Hospital and School.

Degree of Bachelor of Dental Surgery (*B.D.S.*).—(*a*) For students taking their complete course of instruction in the University. Such students must pass the same matriculation tests as medical students, and the same pre-registration examination in Inorganic Chemistry and Physics. After registration students must spend five years in the University, on attendance on such subjects as Senate, on the recommendation of the Board of the Faculty of Medicine, may from time to time determine. They must attend the practice of the Newcastle-upon-Tyne Dental Hospital for not less than two and a half years. Six months of this time must be devoted to the study of the higher branches of dental science. There are four examinations.

The subjects of the *first* examination are Biology and Organic Chemistry, of the same standard as for medical students; and Dental Mechanics and Metallurgy.

The subjects of the *second* examination are Anatomy, Physiology, Dental Anatomy and Histology.

The subjects of the *third* examination are Pathology and Bacteriology, Dental Materia Medica and Therapeutics, and Practical Dental Mechanics.

The subjects of the *final* examination are Medicine, Surgery, Dental Surgery and Pathology, and Orthodontia and Operative Dental Surgery. In this subject knowledge of a much higher standard, and more advanced practical work, will be required than for the Licence in Dental Surgery.

(*b*) For candidates possessing a Licence in Dental Surgery of a British University. Candidates must study for at least one year in the University. During such year they must (*a*) attend a course of instruction in Pathology and Bacteriology, and (*b*) spend at least six months in the Newcastle-upon-Tyne Dental Hospital in the study and practice of the higher branches of dental science. They must also pass the third and final examinations for the degree of Bachelor of Dental Surgery.

Degree of Master of Dental Surgery (*M.D.S.*)—Every candidate for this degree must be a Bachelor of Dental Surgery of the University of not less than two years' standing, and present an essay embodying original work and research in some subject connected with dentistry. They must also perform to the satisfaction of the examiners a piece of special dental work demanding a high degree of skill and experience.

The examinations are held concurrently with the medical examinations, and the fees payable by candidates for the Licence in Dental Surgery are as follows: First Examination, £2 10*s.*; Second Examination, £2 10*s.*; Third Examination, £3 10*s.*; Final Examination, £3 10*s.*; fee for Licence, £3; total, £15. For re-examination: First Examination, £1 10*s.*; Second Examination, £2; Third Examination, £2 (in one part only, £1); Fourth Examination, £2. The practical examinations in dentistry are conducted at the Newcastle Dental Hospital.

---

† See previous page.

‡ A student who has diligently attended an approved course of Elementary Biology in a secondary school or other teaching institution recognised by the University may be admitted to a Professional Examination in Elementary Biology immediately after his registration as a dental student.

It has a floor space of over 6000 square feet, and affords accommodation for about 100 dental chairs, with the necessary equipment of the most modern type, for the use of the Dressers, who, under the supervision of the Staff, perform the various operations of Dental Surgery. The members of the staff attend every morning and afternoon to give demonstrations and otherwise assist students in their work in the Conservation Room and Prosthetic Laboratory. The Probationers' Laboratory is supervised by three of the staff demonstrators, and instruction is given in operative dentistry on a "mannikin" to students during their first three months of clinical study. Students in Dental Prosthetics are received, and a graded, systematic, and full course of instruction, extending over two years, is carried out under the supervision of the Director of the Prosthetic Laboratory, assisted by two demonstrators and five mechanics. Dental students have the opportunity of attending at this hospital the whole course of instruction required by the examining board for the B.D.S. Lond. or L.D.S. Eng.—viz., the complete course in dental prosthetics, the special lectures and practice of the Dental Department, and the general lectures and practice of the Medical School. The fees for these two courses may be paid separately or together, or they may be combined with the fees required to be paid for the course for a medical diploma. Students who enter for a medical as well as a dental diploma are allowed to pursue their study of Dentistry during any period of their medical course most convenient to themselves without further charge. Two Entrance Scholarships are awarded in July of each year, a War Memorial Scholarship in Arts of the annual value of £40 for four years; and a Science Scholarship of the value of £40 per annum for not more than four years. Prizes of the aggregate value of £40 are awarded for general proficiency and for skill in Operative Dentistry. The Newland-Pedley Gold Medal for Operative Dentistry is also awarded annually. Dental students are eligible for admission to the Residential College and enjoy the privileges of students in the Medical School. Application should be made to the Dean of the Medical School.

Appointments: All appointments are made according to the merits of the candidates, as determined by a committee of the Dental Staff. Eighteen house surgeons, 15 assistant house surgeons, and 15 clinical assistants, and four student demonstrators of Dental Histology are appointed annually. The following appointments are held by students: Full surgeon's dresser, assistant surgeon's dresser, orthodontia dresser, casualty dresser, clerk to the anæsthetist, dresser in the gas extraction and ordinary extraction rooms, and probationary dresser.

London Hospital.—This school is a part of the London Hospital and Medical College, and is fully equipped on the most modern lines and with the latest appliances. It provides a complete curriculum in all subjects for the B.D.S. Degree and for the L.D.S. Diploma, and is admirably adapted for the purpose of teaching. The Conservation Room is well lighted and ventilated and fitted with pump chairs of the latest pattern; the fountain spittoons at many of the chairs have been specially designed. Each spittoon has attached to it a saliva ejector, hot and cold water, compressed air, gas and electric current, also a swing bracket to carry the students' cabinet. Electric sterilisers are supplied in each department and motor engines where required. The School possesses in addition to the Theatres, Laboratories and Museums in the College, a special Museum of Dental Anatomy and Surgery, Operative Dentistry, Prosthetic and Extraction Rooms, and Laboratories for Practical Dental Métallurgy and Dental Prosthesis. The extension of the school will be undertaken during the ensuing session. A systematic course of instruction in Dental Prosthesis is arranged for pupils. The up-to-date Laboratory contains every modern apparatus and is in charge of a skilled curator and his assistants. Connected with the Medical College and Dental School are a Library, Athenæum, Clubs' Union, Dining Hall with moderate tariff, Students' Hostel, and an Athletic Ground. For full particulars as to Scholarships and Prizes, fees and course of study advised, apply to the Dean, Prof. William Wright, who will be glad to make arrangements for anyone wishing to see the Dental School and Medical College.

London (Royal Free Hospital) School of Medicine for Women.—Full courses are arranged for women students, in conjunction with the Royal Dental Hospital, Leicester-square, for the study of dentistry, and in preparation for the B.D.S. Degree of the University of London and the Licence in Dental Surgery of the Royal College of Surgeons of England, at the London (Royal Free Hospital) School of Medicine for Women.

PROVINCIAL.

Birmingham Dental Hospital, Great Charles-street.—Dean: Mr. W. T. Madin. The Dental Hospital was founded in 1858, and was recognised by the Royal College of Surgeons in 1880 for the teaching of Dental Students. Having an annual attendance of about 21,000 patients, it affords every advantage for students about to enter the profession to acquire a thorough practical knowledge, as required by the Medical Council. The present Hospital was opened on July 6th, 1905. It has accommodation for 50 students. The equipment is in accordance with the most modern requirements for the efficient teaching and practice of Dental Surgery. The operations performed annually average 41,000, including 9000 gold and other fillings, and many cases of crowns, bridges, porcelain inlays, and regulations. By arrangements with the Birmingham University and with the General and Queen's Hospitals the entire course of Lectures, Hospital Practice, &c., may be completed for an inclusive fee of £144 4s. 6d., or including Mechanical Pupilage, £255 15s. 9d., inclusive of Examination fees for L.D.S. Birm. The instruments and materials necessary for Hospital Practice cost about £45. The Composition Fee for the courses required for the L.D.S. of the University, or any of the Corporations alone, is £75, payable in two annual instalments at the commencement of the first and second years; that for the courses required for the L.D.S. and the Degree in Dentistry of the University is £93 15s.; that for the L.D.S. in combination with the M.R.C.S. and L.R.C.P. is £115; and that for the M.B., Ch.B., and B.D.S. is £120. All of these composition fees are payable in two annual instalments at the commencement of the first and second years. Each of these fees covers the cost of the courses given at the University for the qualifications indicated, but does not include fees for Hospital teaching, nor Pre-Dental year Chemistry and Physics. For two years' dental hospital practice the fee is £26 5s., payable in two instalments of £13 2s. 6d. each at the commencement of the first and second (hospital) years respectively. For two years' mechanical pupilage, £111 11s. 3d., which may be paid in two annual instalments of £65 12s. 6d. and £45 18s. 9d. respectively; mechanical pupils may join for a probationary period of one month, fee £6 11s. 3d., which is deducted upon payment of the full amount. For general surgical hospital practice, lectures, and demonstrations: Surgery, two winters, £13 2s. 6d. One Entrance Scholarship is offered annually of the value of £37 10s. It is awarded to the student who, entering for the Dental Degree of the University in October, or having entered not earlier than the previous April, shall pass the best examination in the subjects studied during his apprenticeship. Candidates must be under the age of 21 years. Application for admission, together with a certificate of birth, must be sent to the Dean of the Medical Faculty, Mr. William F. Haslam, on or before Oct. 15th.

Leeds University School of Dentistry.—The School of Dentistry is adequately equipped to provide for the complete training of the dental student. The School forms a part of the Leeds School of Medicine, whilst the instruction in clinical and mechanical dentistry is carried out in the Dental Hospital at the General

University regulations during a period of not less than four years subsequently to passing the preliminary examination and the passing of the further examination in Chemistry and Physics. Two years must be passed in the University, one at least being subsequent to the passing of the First Examination.

First Examination: The subject of the examination is Biology. Candidates must have attended a course of instruction for one year. Second Examination: The subjects of the examination are Anatomy and Physiology, Dental Anatomy and Physiology, Dental Mechanics, Dental Metallurgy. Final Examination: The subjects of the examination are: Part I., Pathology and Bacteriology; Part II., Medicine and Surgery, Dental Surgery, including Materia Medica and Therapeutics. Candidates for Part II. must have completed the fourth year of professional study.

The Dental Composition Fee is £25 for each year of the course. In addition a fee of £50 is payable each year the student receives instruction in Mechanical Dentistry in the Dental Department.

National University of Ireland.*—At this University there is a Diploma in Public Health, a B.Sc. in Public Health, and a D.Sc. in Public Health. The Diploma may be granted to matriculated or non-matriculated students of the University who shall have completed approved courses of study and shall have passed the prescribed examinations, provided that it shall not be granted except to a registered medical practitioner. Candidates may present themselves for the examination after an interval of not less than 12 months from the time of obtaining a registrable qualification. The curriculum extends over a period of not less than nine calendar months. Every candidate must produce a certificate that he has attended practical instruction in a laboratory, approved by the University, in Chemistry, Bacteriology, and the Pathology of the diseases of animals transmissible to man. The examination consists of two parts, which may be passed separately or together. Part I. comprises the following subjects: Chemistry, Meteorology and Climatology, and Sanitary Engineering and Architecture. Part II. comprises the following subjects: Bacteriology, Hygiene, Sanitary Law, and Vital Statistics. The examination in each part will be oral and practical as well as written.

For the B.Sc. in Public Health a candidate shall not be admitted unless he (*a*) shall have received the degrees of M.B., B.Ch., and B.A.O. at least one year previously; (*b*) shall have pursued an approved course of study in the Faculty of Medicine; and (*c*) shall have passed the prescribed examination. In addition to D.P.H. course the candidate will be required to take up (1) a Special Course of Pathology; (2) Bacteriology; and (3) Advanced Course in Hygiene. Each of these courses lasts three months.

Queen's University of Belfast.—The following degrees and diplomas are now conferred: Licentiate in Dental Surgery, Bachelor of Dental Surgery, and Master of Dental Surgery. Lecturers have been appointed in Dental Surgery, Dental Mechanics, Dental Metallurgy and Materia Medica, and Orthodontia.

TEACHING INSTITUTIONS IN DENTISTRY.

Of teaching institutions those connected with the several universities have now been described in some detail, but in addition to these there are a number of institutions which offer facilities to dental students and which are here set out under their localities.

LONDON.

Royal Dental Hospital of London, School of Dental Surgery, Leicester-square.—A school of the University of London, and women are now admitted as students and are eligible for all hospital appointments and school prizes. The school provides the special dental education required by the Royal College of Surgeons for the Licence in Dental Surgery. The general part of the curriculum may be taken at any general hospital. The hospital is open from 9 A.M. to 5 P.M., there being one staff for the morning and another for the afternoon of each day. Pupils are received for the training in dental mechanics recognised by the curriculum. The instructors at the commencement of each session give a course of lectures on Operative Dental Surgery. The five house surgeoncies are held for six months each and are open to all qualified students. The lecturers, in addition to their lectures, give special demonstrations on the Microscopy of Dental Anatomy and Dental Surgery. The lecturer on Dental Mechanics also gives practical demonstrations in the laboratory. There is an Entrance Scholarship in Chemistry and Physics of the value of £50. One Entrance Scholarship in Dental Mechanics and Metallurgy, value £25, open to pupils of the Hospital only. One Entrance Scholarship of £25 in Dental Mechanics, open to pupils of private practitioners. The Saunders Scholarship of £20 and Saunders Prize of £5 awarded to second year students. The Storer Bennett Research Scholarship for Scientific Research in any branch of Dental Surgery, value £50, is awarded triennially. The Alfred Woodhouse Scholarship of £35 and the Robert Woodhouse Prize of £10 for Practical Dental Surgery. Prizes and certificates are awarded by the lecturers for the best examinations in the subjects of their respective courses at the end of the summer and winter sessions. Fee for two years' hospital practice required by the curriculum, including lectures, £70 in one payment, or £73 10*s.* in two yearly instalments. The curriculum requires two years to be passed at a General Hospital; the fee for this is about £68 5*s.* Both hospitals can be attended simultaneously. For the lectures in Chemistry and Physics for the Preliminary Science Examination £13 13*s.* The fee for the instruction in Dental Mechanics and the two years' hospital practice required by the curriculum is £200 if paid in one instalment, or 200 guineas if paid in three equal instalments. The fee for tuition in Dental Mechanics is £70 per annum; for one year's hospital practice £28. The Winter Session opens on Oct. 1st.

University College Hospital Dental School, corner of Great Portland and Devonshire-streets, W.—This Hospital and School has recently been thoroughly reorganised, and is now fully equipped with all the most modern appliances. Students are entered as students of University College Hospital, and, as such, attend the classes of Anatomy and Physiology in University College, which is a few minutes' walk from the Dental Department in Great Portland-street, hitherto known as the National Dental Hospital, the first Dental School to admit Women Students. Practical courses to comply with the R.C.S. curriculum are held. Clinical Lectures and Demonstrations are given, and each student on entering passes through a preliminary course under a demonstrator. *Composition Fees*: Comprising two years' Dental Mechanics, Anatomy, Physiology; two years' Hospital Practice, Medicine, Surgery, and Dental Lectures (four years): 1st year, £56; 2nd year, £84; 3rd year, £64; 4th year, £32; total, £236. Medical Men: Two years' Mechanics, and Dental Practice and Lectures: 1st year, £102 6*s.*; 2nd year, £70; total, £172 6*s.* For a six years' course of medical and dental education comprising the whole of the dental curriculum and the curriculum for the M.R.C.S., L.R.C.P. diplomas: 1st year, £91; 2nd year, £70; 3rd year, £73; 4th year, £60; 5th year, £73; 6th year, £49; total, £416. in six instalments payable in advance.

Guy's Hospital.—The work of the Dental Department begins daily at 9 A.M. both in the extraction rooms and in the conservation room. The Extraction Rooms: There is ample accommodation for ordinary extractions and anæsthetic extractions, together with waiting- and retiring-rooms. Patients are admitted between 8.45 and 9.30 A.M., and are seen by the dental surgeon for the day, the staff demonstrator, the dental house surgeon, and the dressers The Conservation Room is open from 9 A.M. till 5 P.M.

---

* No returns.

It has a floor space of over 6000 square feet, and affords accommodation for about 100 dental chairs, with the necessary equipment of the most modern type, for the use of the Dressers, who, under the supervision of the Staff, perform the various operations of Dental Surgery. The members of the staff attend every morning and afternoon to give demonstrations and otherwise assist students in their work in the Conservation Room and Prosthetic Laboratory. The Probationers' Laboratory is supervised by three of the staff demonstrators, and instruction is given in operative dentistry on a "mannikin" to students during their first three months of clinical study. Students in Dental Prosthetics are received, and a graded, systematic, and full course of instruction, extending over two years, is carried out under the supervision of the Director of the Prosthetic Laboratory, assisted by two demonstrators and five mechanics. Dental students have the opportunity of attending at this hospital the whole course of instruction required by the examining board for the B.D.S. Lond. or L.D.S. Eng.—viz., the complete course in dental prosthetics, the special lectures and practice of the Dental Department, and the general lectures and practice of the Medical School. The fees for these two courses may be paid separately or together, or they may be combined with the fees required to be paid for the course for a medical diploma. Students who enter for a medical as well as a dental diploma are allowed to pursue their study of Dentistry during any period of their medical course most convenient to themselves without further charge. Two Entrance Scholarships are awarded in July of each year, a War Memorial Scholarship in Arts of the annual value of £40 for four years; and a Science Scholarship of the value of £40 per annum for not more than four years. Prizes of the aggregate value of £40 are awarded for general proficiency and for skill in Operative Dentistry. The Newland-Pedley Gold Medal for Operative Dentistry is also awarded annually. Dental students are eligible for admission to the Residential College and enjoy the privileges of students in the Medical School. Application should be made to the Dean of the Medical School.

Appointments: All appointments are made according to the merits of the candidates, as determined by a committee of the Dental Staff. Eighteen house surgeons, 15 assistant house surgeons, and 15 clinical assistants, and four student demonstrators of Dental Histology are appointed annually. The following appointments are held by students: Full surgeon's dresser, assistant surgeon's dresser, orthodontia dresser, casualty dresser, clerk to the anæsthetist, dresser in the gas extraction and ordinary extraction rooms, and probationary dresser.

London Hospital.—This school is a part of the London Hospital and Medical College, and is fully equipped on the most modern lines and with the latest appliances. It provides a complete curriculum in all subjects for the B.D.S. Degree and for the L.D.S. Diploma, and is admirably adapted for the purpose of teaching. The Conservation Room is well lighted and ventilated and fitted with pump chairs of the latest pattern; the fountain spittoons at many of the chairs have been specially designed. Each spittoon has attached to it a saliva ejector, hot and cold water, compressed air, gas and electric current, also a swing bracket to carry the students' cabinet. Electric sterilisers are supplied in each department and motor engines where required. The School possesses in addition to the Theatres, Laboratories and Museums in the College, a special Museum of Dental Anatomy and Surgery, Operative Dentistry, Prosthetic and Extraction Rooms, and Laboratories for Practical Dental Metallurgy and Dental Prosthesis. The extension of the school will be undertaken during the ensuing session. A systematic course of instruction in Dental Prosthesis is arranged for pupils. The up-to-date Laboratory contains every modern apparatus and is in charge of a skilled curator and his assistants. Connected with the Medical College and Dental School are a Library, Athenæum, Clubs' Union, Dining Hall with moderate tariff, Students' Hostel, and an Athletic Ground. For full particulars as to Scholarships and Prizes, fees and course of study advised, apply to the Dean, Prof. William Wright, who will be glad to make arrangements for anyone wishing to see the Dental School and Medical College.

London (Royal Free Hospital) School of Medicine for Women.—Full courses are arranged for women students, in conjunction with the Royal Dental Hospital, Leicester-square, for the study of dentistry, and in preparation for the B.D.S. Degree of the University of London and the Licence in Dental Surgery of the Royal College of Surgeons of England, at the London (Royal Free Hospital) School of Medicine for Women.

PROVINCIAL.

Birmingham Dental Hospital, Great Charles-street.—Dean: Mr. W. T. Madin. The Dental Hospital was founded in 1858, and was recognised by the Royal College of Surgeons in 1880 for the teaching of Dental Students. Having an annual attendance of about 21,000 patients, it affords every advantage for students about to enter the profession to acquire a thorough practical knowledge, as required by the Medical Council. The present Hospital was opened on July 6th, 1905. It has accommodation for 50 students. The equipment is in accordance with the most modern requirements for the efficient teaching and practice of Dental Surgery. The operations performed annually average 41,000, including 9000 gold and other fillings, and many cases of crowns, bridges, porcelain inlays, and regulations. By arrangements with the Birmingham University and with the General and Queen's Hospitals the entire course of Lectures, Hospital Practice, &c., may be completed for an inclusive fee of £144 4*s.* 6*d.*, or including Mechanical Pupilage, £255 15*s.* 9*d.*, inclusive of Examination fees for L.D.S. Birm. The instruments and materials necessary for Hospital Practice cost about £45. The Composition Fee for the courses required for the L.D.S. of the University, or any of the Corporations alone, is £75, payable in two annual instalments at the commencement of the first and second years; that for the courses required for the L.D.S. and the Degree in Dentistry of the University is £93 15*s.*; that for the L.D.S. in combination with the M.R.C.S. and L.R.C.P. is £115; and that for the M.B., Ch.B., and B.D.S. is £120. All of these composition fees are payable in two annual instalments at the commencement of the first and second years. Each of these fees covers the cost of the courses given at the University for the qualifications indicated, but does not include fees for Hospital teaching, nor Pre-Dental year Chemistry and Physics. For two years' dental hospital practice the fee is £26 5*s.*, payable in two instalments of £13 2*s.* 6*d.* each at the commencement of the first and second (hospital) years respectively. For two years' mechanical pupilage, £111 11*s.* 3*d.*, which may be paid in two annual instalments of £65 12*s.* 6*d.* and £45 18*s.* 9*d.* respectively; mechanical pupils may join for a probationary period of one month, fee £6 11*s.* 3*d.*, which is deducted upon payment of the full amount. For general surgical hospital practice, lectures, and demonstrations: Surgery, two winters, £13 2*s.* 6*d.* One Entrance Scholarship is offered annually of the value of £37 10*s.* It is awarded to the student who, entering for the Dental Degree of the University in October, or having entered not earlier than the previous April, shall pass the best examination in the subjects studied during his apprenticeship. Candidates must be under the age of 21 years. Application for admission, together with a certificate of birth, must be sent to the Dean of the Medical Faculty, Mr. William F. Haslam, on or before Oct. 15th.

Leeds University School of Dentistry.—The School of Dentistry is adequately equipped to provide for the complete training of the dental student. The School forms a part of the Leeds School of Medicine. whilst the instruction in clinical and mechanical dentistry is carried out in the Dental Hospital at the General

University regulations during a period of not less than four years subsequently to passing the preliminary examination and the passing of the further examination in Chemistry and Physics. Two years must be passed in the University, one at least being subsequent to the passing of the First Examination.

First Examination: The subject of the examination is Biology. Candidates must have attended a course of instruction for one year. Second Examination: The subjects of the examination are Anatomy and Physiology, Dental Anatomy and Physiology, Dental Mechanics, Dental Metallurgy. Final Examination: The subjects of the examination are: Part I., Pathology and Bacteriology; Part II., Medicine and Surgery, Dental Surgery, including Materia Medica and Therapeutics. Candidates for Part II. must have completed the fourth year of professional study.

The Dental Composition Fee is £25 for each year of the course. In addition a fee of £50 is payable each year the student receives instruction in Mechanical Dentistry in the Dental Department.

NATIONAL UNIVERSITY OF IRELAND.*—At this University there is a Diploma in Public Health, a B.Sc. in Public Health, and a D.Sc. in Public Health. The Diploma may be granted to matriculated or non-matriculated students of the University who shall have completed approved courses of study and shall have passed the prescribed examinations, provided that it shall not be granted except to a registered medical practitioner. Candidates may present themselves for the examination after an interval of not less than 12 months from the time of obtaining a registrable qualification. The curriculum extends over a period of not less than nine calendar months. Every candidate must produce a certificate that he has attended practical instruction in a laboratory, approved by the University, in Chemistry, Bacteriology, and the Pathology of the diseases of animals transmissible to man. The examination consists of two parts, which may be passed separately or together. Part I. comprises the following subjects: Chemistry, Meteorology and Climatology, and Sanitary Engineering and Architecture. Part II. comprises the following subjects: Bacteriology, Hygiene, Sanitary Law, and Vital Statistics. The examination in each part will be oral and practical as well as written.

For the B.Sc. in Public Health a candidate shall not be admitted unless he (*a*) shall have received the degrees of M.B., B.Ch., and B.A.O. at least one year previously; (*b*) shall have pursued an approved course of study in the Faculty of Medicine; and (*c*) shall have passed the prescribed examination. In addition to D.P.H. course the candidate will be required to take up (1) a Special Course of Pathology; (2) Bacteriology; and (3) Advanced Course in Hygiene. Each of these courses lasts three months.

QUEEN'S UNIVERSITY OF BELFAST.—The following degrees and diplomas are now conferred: Licentiate in Dental Surgery, Bachelor of Dental Surgery, and Master of Dental Surgery. Lecturers have been appointed in Dental Surgery, Dental Mechanics, Dental Metallurgy and Materia Medica, and Orthodontia.

TEACHING INSTITUTIONS IN DENTISTRY.

Of teaching institutions those connected with the several universities have now been described in some detail, but in addition to these there are a number of institutions which offer facilities to dental students and which are here set out under their localities.

LONDON.

Royal Dental Hospital of London, School of Dental Surgery, Leicester-square.—A school of the University of London, and women are now admitted as students and are eligible for all hospital appointments and school prizes. The school provides the special dental education required by the Royal College of Surgeons for the Licence in Dental Surgery. The general part of the curriculum may be taken at any general hospital. The hospital is open from 9 A.M. to 5 P.M., there being one staff for the morning and another for the afternoon of each day. Pupils are received for the training in dental mechanics recognised by the curriculum. The instructors at the commencement of each session give a course of lectures on Operative Dental Surgery. The five house surgeoncies are held for six months each and are open to all qualified students. The lecturers, in addition to their lectures, give special demonstrations on the Microscopy of Dental Anatomy and Dental Surgery. The lecturer on Dental Mechanics also gives practical demonstrations in the laboratory. There is an Entrance Scholarship in Chemistry and Physics of the value of £50. One Entrance Scholarship in Dental Mechanics and Metallurgy, value £25, open to pupils of the Hospital only. One Entrance Scholarship of £25 in Dental Mechanics, open to pupils of private practitioners. The Saunders Scholarship of £20 and Saunders Prize of £5 awarded to second year students. The Storer Bennett Research Scholarship for Scientific Research in any branch of Dental Surgery, value £50, is awarded triennially. The Alfred Woodhouse Scholarship of £35 and the Robert Woodhouse Prize of £10 for Practical Dental Surgery. Prizes and certificates are awarded by the lecturers for the best examinations in the subjects of their respective courses at the end of the summer and winter sessions. Fee for two years' hospital practice required by the curriculum, including lectures, £70 in one payment, or £73 10*s*. in two yearly instalments. The curriculum requires two years to be passed at a General Hospital; the fee for this is about £68 5*s*. Both hospitals can be attended simultaneously. For the lectures in Chemistry and Physics for the Preliminary Science Examination £13 13*s*. The fee for the instruction in Dental Mechanics and the two years' hospital practice required by the curriculum is £200 if paid in one instalment, or 200 guineas if paid in three equal instalments. The fee for tuition in Dental Mechanics is £70 per annum; for one year's hospital practice £28. The Winter Session opens on Oct. 1st.

University College Hospital Dental School, corner of Great Portland and Devonshire-streets, W.—This Hospital and School has recently been thoroughly reorganised, and is now fully equipped with all the most modern appliances. Students are entered as students of University College Hospital, and, as such, attend the classes of Anatomy and Physiology in University College, which is a few minutes' walk from the Dental Department in Great Portland-street, hitherto known as the National Dental Hospital, the first Dental School to admit Women Students. Practical courses to comply with the R.C.S. curriculum are held. Clinical Lectures and Demonstrations are given, and each student on entering passes through a preliminary course under a demonstrator. Composition Fees: Comprising two years' *Dental* Mechanics, Anatomy, Physiology; two years' Hospital Practice, Medicine, Surgery, and Dental Lectures (four years): 1st year, £56; 2nd year, £84; 3rd year, £64; 4th year, £32; total, £236. Medical Men: Two years' Mechanics. and Dental Practice and Lectures: 1st year, £102 6*s*.; 2nd year, £70; total, £172 6*s*. For a six years' course of medical and dental education comprising the whole of the dental curriculum and the curriculum for the M.R.C.S., L.R.C.P. diplomas: 1st year, £91; 2nd year, £70; 3rd year, £73; 4th year, £60; 5th year, £73; 6th year, £49; total, £416. in six instalments payable in advance.

Guy's Hospital.—The work of the Dental Department begins daily at 9 A.M. both in the extraction rooms and in the conservation room. The Extraction Rooms: There is ample accommodation for ordinary extractions and anæsthetic extractions, together with waiting- and retiring-rooms. Patients are admitted between 8.45 and 9.30 A.M., and are seen by the dental surgeon for the day, the staff demonstrator, the dental house surgeon, and the dressers The Conservation Room is open from 9 A.M. till 5 P.M.

Reviews and Notices of Books.

DISEASES OF MIDDLE LIFE.

The Prevention, Recognition, and Treatment of the Morbid Processes of Special Significance in this Critical Life Period. Comprising 22 original articles by various eminent authorities. Edited by FRANK A. CRAIG, M.D., Associate Director of the Clinical and Sociological Department of the Henry Phipps Institute of the University of Pennsylvania. Philadelphia: F. A. Davis Company. In two volumes. Pp. 1871. $15.

ATTENTION is more and more being directed to the early stage of many diseases and to the best means of preventing their more serious development. We are often reminded that middle life is the danger period for a great variety of functional and organic breakdowns. The aim of the monographs in these two readable volumes is to assist the practitioner to detect and to treat the early departures from health in middle life.

It is difficult to deal comprehensively with the therapeutic problems involved. There is, for example, the systematic treatment of incipient and chronic disease at health resorts and spas, a large section of the habitual visitors being middle-aged invalids. To this branch of therapeutics only occasional reference is made in these volumes. We select a few examples of the broad and helpful spirit in which the more important sections are discussed. Diet is excellently dealt with by Dr. C. B. Farr, of Akron, Ohio. He calls attention to the diet-requirements in middle life, and refers to the plus or minus basal metabolism of some middle-age disorders, and to the small demand for extra calories in some occupations, such as 44 for a physician or tailor, as against 378 for a man sawing wood. The view of this authority that there is little real proof of intestinal auto-intoxication is supported by another writer in this work, but contradicted by a third. There is a timely and suggestive account of the liabilities and dangers of hypernutrition and of subnutrition. In the section on occupation, Prof. E. R. Hayhurst (Ohio State University) asserts the principle that producers become dependents only by mishap, and that debility-dependence ought not to begin until well over 60. He points out that convalescence can be much expedited by graduated activity of a kind interesting to the patient. The normal temperature for work-rooms, 68° F. for sedentary occupations and downwards, is higher than that prescribed by English authorities, but the prime importance of adequate cooling of the body is not disputed. Prof. J. E. Talley (University of Pennsylvania) gives a more favourable prognosis for disease of the heart in middle life than was current a few years ago. For example, he states that extra-systoles in the third and fourth decades, from which many medical men suffer, usually disappear, or anyhow diminish, in the fifth decade, if the digestion is attended to. Paroxysmal tachycardia coming on in middle life is not so very serious; and cases of auricular flutter, associated with arteriosclerosis, in later life often do fairly well. Again, auricular fibrillation may go on for years, the prognosis depending on the reaction to digitalis. Quinidine, in the author's experience, abolishes fibrillation in 50 per cent. of the cases. He accepts the general view that the prognosis of valvular disease depends on the condition of the myocardium. The value of spirometer measurements in the prognosis of heart affections is emphasised. As showing the prevalence of these affections, it is stated that there are 34 special cardiac clinics in New York, and need for more convalescent beds for "potential cardiac" cases.

Prof. G. M. Piersol (Pennsylvania University) gives an admirable account of the progressive symptomatology of hypertension, following Osler, Adami, Janeway, and others in considering this common disturbance of middle age as antecedent to sclerosis and due to habitual arteriolar spasm. Arteriolar spasm, increased peripheral resistance, increased arterial pressure, hypertrophy of the left ventricle, and myocardial failure form an obvious morbid sequence. The author seems to adopt the view that this "compensation" is conservative, and essential to maintain the circulation. On the other hand, it might be claimed that, if the chain of causation is correctly stated, any method of treatment, such as venesection or warm bathing, that relieves peripheral spasm, will be more truly conservative. Dr. O. H. P. Pepper, in a valuable article on Diseases of the Kidney, remarks that, whilst insurance statistics show that the albuminuria of adolescents does not lead to nephritis in later years, the albuminuria which develops in middle life is a sure sign of kidney disease. When the excretory renal function is reduced, as in middle life, its estimation becomes a matter of importance. The author discusses the signs and symptoms of renal insufficiency and the tests by which it may be detected, concluding that the response of the kidney to water, in minimal or excess quantities, affords a better criterion in chronic nephritis than phenol-sulphonephthalein. These two methods, with the determination of the blood-urea nitrogen, are the three tests of renal function most useful in middle age. Chronic nephritis without œdema is, in the writer's belief, increasing in frequency in middle age. Diabetes mellitus, according to Dr. H. K. Mohler, is becoming more common in America. He claims that Allen's principles of diet have prolonged the life of the adult diabetic by three years. A short section on insulin was added after the book was written.

In a section on Diseases of the Respiratory Tract, the editor expresses an interesting warning. Forced breathing, he thinks, may activate an incipient or dormant tuberculosis, and there is no advantage in increasing the air capacity of healthy lungs excepting in cases of faulty development or improper breathing, or for special requirements like singing or running. Again, in middle-aged persons with fibrous tuberculosis fresh air may cause dangerous chilling, but with care the majority of such cases will be able to "play a minor part in workaday life," although only a few can follow "the abnormal life of the average individual." Dr. Chandler Walker (Harvard Medical School), dealing with bronchial asthma, claims better results from protein therapy than are usually claimed in this country. As to "colds," he considers that they invariably signify lowered physical resistance, too many nasal operations are performed in America, and too much mucous membrane removed. Autogenous vaccines are praised.

In writing on the Gastric Disturbances of Middle Life, Prof. Julius Friedenwald and Dr. T. H. Morrison (both of the University of Maryland) throw out many arresting suggestions not all of which will be accepted. In their experience gastric neuroses form more than half the stomach cases. These are commonest in middle life, often occur in robust subjects, and are sometimes unexpectedly sudden in their onset, like cancer. The old observation of Hutchinson is confirmed, that secondary gastric symptoms are present in the great majority (80 per cent.) of early cases of pulmonary tuberculosis. The progressive sclerotic degeneration of the secretory structure, first demonstrated by Fenwick, probably accounts for the diminution of motility and secretion and frequent dyspepsia in later life, and the achylia gastrica of many elderly persons. Dr. Anthony Basler (Christ's, N.J.), from his experience of chronic intestinal cases, regards the colon as the chief cause of disease in middle life, but is strongly opposed to surgical intervention, regarding operation upon the colon as unwarrantable unless bona fide obstruction is present. He makes an exception for chronic colitis with follicular ulceration, in which appendicostomy and trans-irrigation of the large bowel give, at least for a time, good results. Much of the current treatment of colon disorders is, in his view, based on rash assumptions from laboratory findings. "The germicidal effect of drugs in the

Infirmary. The courses of study are mainly designed to meet the requirements of the B.Ch.D. and L.D.S. Leeds, but every opportunity is afforded to students preparing for the degrees or diplomas of other licensing bodies. Full-time demonstrators give the instruction in clinical dental surgery and prosthetic dentistry, which is carried out under the supervision and direction of members of the Honorary Staff, two of whom are in attendance each day. Special facilities are provided for instruction in Orthodontia and Dental Radiography. Prizes are offered for competition to pupils and students in their respective years of study. Communications should be addressed to the Warden, School of Dentistry, The University, Leeds, from whom a prospectus may be obtained.

Dental Hospital of Manchester.—This hospital is in association for teaching purposes with the University of Manchester and the Royal Infirmary, and is in the centre of a very large population. Courses of study are provided to meet the requirements of the various examining bodies, including those of the University of Manchester for the qualifications L.D.S. and B.D.S., and the L.D.S. of the Royal College of Surgeons of England. Clinical instruction is given in Dental Prosthetics, Operative Dentistry, Diagnosis and Extraction, Orthodontics, Dental Surgery, Radiography, and Anæsthetics by specially appointed Clinical Teachers.

For the whole course of hospital instruction for the L.D.S. (including two years' mechanical training) the fee is £131 5*s.*, paid in instalments. For the two years' Operative Course only, £26 5*s.*, paid in two instalments. For the whole course of hospital instruction for the B.D.S. degree (including mechanical training), £168, paid in instalments. Additional practice in Dental Mechanics may be taken by pupils who have already received their mechanical training elsewhere, at a fee of £36 15*s.* for six months. All the courses of instruction are open to women students. Copies of the Prospectus will be forwarded on application to Mr. J. Hilditch Mathews, Dean.

Newcastle-upon-Tyne Dental Hospital and School.—This hospital is centrally situated (within five minutes of the various colleges, infirmary, and railway station); the rooms are well lighted and thoroughly equipped for carrying on the work. Dental surgeons and an anæsthetist attend each morning. A tutorial dental surgeon and a prosthetic tutor is also in attendance. The Composition Fee for the special Dental Lectures and Dental Hospital Practice is £60 4*s.* if paid in one sum, or £62 6*s.* if paid in two instalments of £31 3*s.* The Composition Fee for the Lectures at the Colleges of Medicine and Science is £57 10*s.*; in addition to this there is a library and an athletic fee. The fee for General Hospital Practice at the Royal Victoria Infirmary, Newcastle-upon-Tyne, is £23 2*s.* Medals and Certificates of Merit are granted to students showing certain standards of proficiency in the various classes at the Dental School. The prospectus of the Dental Hospital and School, containing full information, may be obtained from either Mr. J. T. Jameson, 12, Windsor-crescent, Newcastle-upon-Tyne, Dean, or Mr. James Coltman, 13, Ellison-place, Newcastle-upon-Tyne, Vice-Dean.

Devon and Exeter Dental Hospital, 24, Southernhay West, Exeter.—Established 1880.—The hospital is open on Mondays, Tuesdays, Wednesdays, Thursdays, Fridays, and Saturdays, and patients are admitted between the hours of 9.30 and 11 A.M. Students attend the practice of the hospital under the control of the medical officers. Honorary treasurer, Mr. J. M. Ackland; secretary, Mr. Albert G. Littlejohn.

SCOTLAND.

The Incorporated Edinburgh Dental Hospital and School.—The Edinburgh Dental Hospital and School is located in spacious and well-equipped buildings at 30, 31, and 32, Chambers-street, and offers special advantages to dental students. The General Courses required for the Dental Diploma may be taken in the Medical School of the Royal Colleges of Physicians and Surgeons or in the University schools. The general hospital attendance and clinical instruction are taken at the Royal Infirmary. The University, Medical Schools, and Royal Infirmary are within three minutes' walk of the Dental Hospital. The special courses are taken in the hospital. The Dental Hospital practice, extending over two years, affords a student ample opportunity for a full acquaintance with every branch of dentistry. The hospital admits a limited number of indentured pupils. They receive their instruction in Mechanical Dentistry concurrently with the general and special courses. A premium of 60 guineas is payable with each such pupil. The practice and lectures of the hospital are recognised by, and qualify for, all the Licensing Boards. The cost of the hospital outfit of instruments is included in the Dental Hospital fee of £42. The minimum cost of classes and Diploma for the whole course of dental instruction amounts to £118 16*s.* Those students who desire to take a Medical and Surgical Diploma in addition to the L.D.S. have in this school admirable facilities for so doing. The triple qualification of the Royal College of Physicians and Surgeons of Edinburgh and the Royal Faculty of Physicians and Surgeons of Glasgow is recommended. The minimum cost of Professional Education, the Triple Qualification, and the Licence in Dental Surgery amounts to £197 3*s.* 6*d.* The Higher Dental Diploma (H.D.D.) of the Royal College of Surgeons affords an opportunity of obtaining a higher qualification subsequent to registration. The Prospectus, with full information, may be obtained by application to the Dean or the Assistant Secretary.

Incorporated Glasgow Dental Hospital, 158, Renfrew-street and 15, Dalhousie-street, Glasgow.—The School is open to Men and Women Students, and Lectures are given on Dental Surgery, Operative Dental Surgery, Orthodontia, Dental Anatomy and Physiology, Pathology, Dental Histology, Dental Mechanics, Crown and Bridge work, Dental Metallurgy, Dental Bacteriology, and Anæsthetics. A new Radiography department has been added. Lectures on general subjects required for Dentistry may be taken at the University or at one of the extramural schools where special provision is made for Dental Students. Composition fee for two years' Hospital Practice and Lectures special to Dentistry, £50 on entry, or in two instalments of £31 10*s.* and £21. A new mechanical laboratory with bench accommodation for 60 pupils and fully equipped with the most modern appliances for teaching practical dental mechanics has recently been added. Fee for two years' tuition, £63, or in two instalments. Full information may be had on application to the Dean.

Glasgow Royal Infirmary (Dental Department).—Mr. W. R. Taylor attends at the Royal Infirmary at 9 A.M. on Wednesdays and other days as arranged. The following course in the curriculum can be taken at St. Mungo's College: Anatomy, six months; Practical Anatomy, nine months; Physiology, six months; Chemistry, six months; Practical Chemistry with Metallurgy, three months; Surgery, six months; Medicine, six months; Materia Medica, three months; Clinical Surgery, six months; Dental Surgery, six months, and attendance for two years on the dental department of the hospital.

IRELAND.

Incorporated Dental Hospital of Ireland, Lincoln-place, Dublin.—All Dental Students who have passed their First Dental Examination in the Royal College of Surgeons in Ireland (or an equivalent examination or examinations) are admissible to the Clinical Instruction of the Hospital. In addition to Clinical Instruction and Special Demonstrations, courses of lectures are given at the hospital on Dental Surgery and Pathology, Mechanical Dentistry, the Administration of Anæsthetics, Orthodontia, Dental Anatomy, and Dental Materia Medica, and instruction in Anæsthetics. Fees: Hospital Practice (each year), £18 18*s.*; Lectures, £5 5*s.* The course in practical Dental Mechanics can be taken in the Hospital Laboratory. Further particulars can be obtained from the Dean.

Reviews and Notices of Books.

DISEASES OF MIDDLE LIFE.

The Prevention, Recognition, and Treatment of the Morbid Processes of Special Significance in this Critical Life Period. Comprising 22 original articles by various eminent authorities. Edited by FRANK A. CRAIG, M.D., Associate Director of the Clinical and Sociological Department of the Henry Phipps Institute of the University of Pennsylvania. Philadelphia: F. A. Davis Company. In two volumes. Pp. 1871. $15.

ATTENTION is more and more being directed to the early stage of many diseases and to the best means of preventing their more serious development. We are often reminded that middle life is the danger period for a great variety of functional and organic breakdowns. The aim of the monographs in these two readable volumes is to assist the practitioner to detect and to treat the early departures from health in middle life.

It is difficult to deal comprehensively with the therapeutic problems involved. There is, for example, the systematic treatment of incipient and chronic disease at health resorts and spas, a large section of the habitual visitors being middle-aged invalids. To this branch of therapeutics only occasional reference is made in these volumes. We select a few examples of the broad and helpful spirit in which the more important sections are discussed. Diet is excellently dealt with by Dr. C. B. Farr, of Akron, Ohio. He calls attention to the diet-requirements in middle life, and refers to the plus or minus basal metabolism of some middle-age disorders, and to the small demand for extra calories in some occupations, such as 44 for a physician or tailor, as against 378 for a man sawing wood. The view of this authority that there is little real proof of intestinal auto-intoxication is supported by another writer in this work, but contradicted by a third. There is a timely and suggestive account of the liabilities and dangers of hypernutrition and of subnutrition. In the section on occupation, Prof. E. R. Hayhurst (Ohio State University) asserts the principle that producers become dependents only by mishap, and that debility-dependence ought not to begin until well over 60. He points out that convalescence can be much expedited by graduated activity of a kind interesting to the patient. The normal temperature for work-rooms, 68° F. for sedentary occupations and downwards, is higher than that prescribed by English authorities, but the prime importance of adequate cooling of the body is not disputed. Prof. J. E. Talley (University of Pennsylvania) gives a more favourable prognosis for disease of the heart in middle life than was current a few years ago. For example, he states that extra-systoles in the third and fourth decades, from which many medical men suffer, usually disappear, or anyhow diminish, in the fifth decade, if the digestion is attended to. Paroxysmal tachycardia coming on in middle life is not so very serious; and cases of auricular flutter, associated with arteriosclerosis, in later life often do fairly well. Again, auricular fibrillation may go on for years, the prognosis depending on the reaction to digitalis. Quinidine, in the author's experience, abolishes fibrillation in 50 per cent. of the cases. He accepts the general view that the prognosis of valvular disease depends on the condition of the myocardium. The value of spirometer measurements in the prognosis of heart affections is emphasised. As showing the prevalence of these affections, it is stated that there are 34 special cardiac clinics in New York, and need for more convalescent beds for "potential cardiac" cases.

Prof. G. M. Piersol (Pennsylvania University) gives an admirable account of the progressive symptomatology of hypertension, following Osler, Adami, Janeway, and others in considering this common disturbance of middle age as antecedent to sclerosis and due to habitual arteriolar spasm. Arteriolar spasm, increased peripheral resistance, increased arterial pressure, hypertrophy of the left ventricle, and myocardial failure form an obvious morbid sequence. The author seems to adopt the view that this "compensation" is conservative, and essential to maintain the circulation. On the other hand, it might be claimed that, if the chain of causation is correctly stated, any method of treatment, such as venesection or warm bathing, that relieves peripheral spasm, will be more truly conservative. Dr. O. H. P. Pepper, in a valuable article on Diseases of the Kidney, remarks that, whilst insurance statistics show that the albuminuria of adolescents does not lead to nephritis in later years, the albuminuria which develops in middle life is a sure sign of kidney disease. When the excretory renal function is reduced, as in middle life, its estimation becomes a matter of importance. The author discusses the signs and symptoms of renal insufficiency and the tests by which it may be detected, concluding that the response of the kidney to water, in minimal or excess quantities, affords a better criterion in chronic nephritis than phenol-sulphonephthalein. These two methods, with the determination of the blood-urea nitrogen, are the three tests of renal function most useful in middle age. Chronic nephritis without œdema is, in the writer's belief, increasing in frequency in middle age. Diabetes mellitus, according to Dr. H. K. Mohler, is becoming more common in America. He claims that Allen's principles of diet have prolonged the life of the adult diabetic by three years. A short section on insulin was added after the book was written.

In a section on Diseases of the Respiratory Tract, the editor expresses an interesting warning. Forced breathing, he thinks, may activate an incipient or dormant tuberculosis, and there is no advantage in increasing the air capacity of healthy lungs excepting in cases of faulty development or improper breathing, or for special requirements like singing or running. Again, in middle-aged persons with fibrous tuberculosis fresh air may cause dangerous chilling, but with care the majority of such cases will be able to "play a minor part in workaday life," although only a few can follow "the abnormal life of the average individual." Dr. Chandler Walker (Harvard Medical School), dealing with bronchial asthma, claims better results from protein therapy than are usually claimed in this country. As to "colds," he considers that they invariably signify lowered physical resistance, too many nasal operations are performed in America, and too much mucous membrane removed. Autogenous vaccines are praised.

In writing on the Gastric Disturbances of Middle Life, Prof. Julius Friedenwald and Dr. T. H. Morrison (both of the University of Maryland) throw out many arresting suggestions not all of which will be accepted. In their experience gastric neuroses form more than half the stomach cases. These are commonest in middle life, often occur in robust subjects, and are sometimes unexpectedly sudden in their onset, like cancer. The old observation of Hutchinson is confirmed, that secondary gastric symptoms are present in the great majority (80 per cent.) of early cases of pulmonary tuberculosis. The progressive sclerotic degeneration of the secretory structure, first demonstrated by Fenwick, probably accounts for the diminution of motility and secretion and frequent dyspepsia in later life, and the achylia gastrica of many elderly persons. Dr. Anthony Basler (Christ's, N.J.), from his experience of chronic intestinal cases, regards the colon as the chief cause of disease in middle life, but is strongly opposed to surgical intervention, regarding operation upon the colon as unwarrantable unless bona fide obstruction is present. He makes an exception for chronic colitis with follicular ulceration, in which appendicostomy and trans-irrigation of the large bowel give, at least for a time, good results. Much of the current treatment of colon disorders is, in his view, based on rash assumptions from laboratory findings. "The germicidal effect of drugs in the intestinal canal is an ostrich proposition," and the claims made for colonic lavage are, in his opinion, unjustified. The metabolic disturbances of infective arthritis are described by Prof. J. A. Lichty (University of Pittsburgh) as operating, like traumatism, to furnish a prepared ground for infective processes. The hypothesis agrees well with the conception of a complex causation for these diseases, and indeed for all disease. Lichty ranges himself with those who deny that the alimentary canal is a common source of infection. Excepting in the case of gonorrhœal arthritis, the use of vaccines has little or no scientific basis. Baths and waters are advocated, the excessive use of heat and undue local reactions being avoided.

The book abounds in fresh and practical observations, and will be of interest to all practitioners who are in touch with the problems of health in middle life. The bibliographies following many of the sections give it an added value. A duplication of paragraphs in one of the articles in the second volume will, no doubt, be corrected in a second edition.

COLLECTED PAPERS.

London School of Tropical Medicine: Department of Helminthology. Collected Papers. Part 5. 1924. Nos. L.–LXVI.

THIS collection of 17 scientific papers, the fifth volume of the series to be issued within the last two years, serves as an index of the activities of the Helminthological Department of the London School of Tropical Medicine, under the directorship of Prof. R. T. Leiper. The volume includes a paper by H. H. Scott on an experimental study of the life-histories of *Hymenolepis fraterna*, Stiles, 1906, and *Hymenolepis longior*, Baylis, 1922, in the mouse, and a number of studies on nematodes of veterinary interest by T. W. M. Cameron and T. Goodey. M. Khalil writes upon the morphology of *Schistosoma bovis*, and Prof. R. T. Leiper contributes an address on the Present-day Teachings on Helminthology in Relation to Public Health.

OTO-RHINO-LARYNGOLOGY.

The Mechanism of the Cochlea: A Restatement of the Resonance Theory of Hearing. By GEORGE WILKINSON, M.B. Camb., F.R.C.S. Eng.; and ALBERT A. GRAY, M.D. Glasg., F.R.S.E. London: Macmillan and Co. 1924. Pp. 253. 12*s.* 6*d.*

THERE are two principal theories of the method whereby the perception of sound, especially of musical sounds, is translated into consciousness, which are called respectively the "resonance" and the "telephone" theories. The resonance theory was originally propounded by von Helmholtz in 1863, and supposes that sounds of different pitch stimulate different portions of the organ of Corti—that is, that sounds are analysed in the cochlea. The telephone theory, put forward in 1886 by Rutherford, premises that the basilar membrane follows the vibrations as a whole, and transmits them as received to the auditory centre in the brain, which performs the task of analysing compound tones and of distinguishing pitch. The resonance theory has remained the most generally accepted, but certain difficulties have prevented its acceptance as a complete explanation. The most important of these difficulties are that the fibres of the basilar membrane are bound together and cannot vibrate separately for tones of every different pitch, and that the differentiation as to length of the basilar fibres is quite inadequate to account for a tuning of these fibres for the whole range of 10 to 11 octaves comprised in the audible scale. The first objection has been met by Dr. Gray's theory of "maximum stimulation" on the analogy of a similar phenomenon in tactile sensation; when a point is pressed on to the skin it is still felt only as a point although, with firm pressure, many surrounding nerve-endings are affected, so, it is held, the nerve-impulses from neighbouring basilar fibres are repressed and only the vibration of the fibre at the maximum point of vibration affects consciousness. Mr. Wilkinson's theory of the fluid load on the fibres of the basilar membrane is designed to meet the second difficulty. The vibration period of a stretched string depends on three factors—length, tension, and mass per unit length, or load. The length and tension of the basilar fibres are known to be differentiated progressively, and Mr. Wilkinson's theory adds that the load on any fibre is the columns of endolymph between it and the fenestræ, and that this is sufficient to allow of a tuning of the fibres to the 10 or 11 octaves required. He has constructed a very ingenious model which gives results that, though necessarily rough, bear out his contention. A full description of this, and of the mathematical formulæ involved, will be found in this book, together with a complete account of the resonance theory, and a consideration of the telephone and other subsidiary theories.

The book deserves the attention of all interested in the subject.

Technique chirurgicale oto-rhino-laryngologique. Deuxième fascicule: Fosses nasales, naso-pharynx, cavités accessoires. By E. J. MOURE, Professor in the Faculty of Medicine of Bordeaux; G. LIÉBAULT, formerly Interne of the Hospitals of Paris; and G. CANUYT, Director of the Oto-Rhino-Laryngological Clinic of Strasbourg. Paris: Libraire Octave Doin. 1924. Pp. 527. Fr.55.

THE aim of this book is to describe in full detail the operative procedures required in the treatment of diseases of the nose, naso-pharynx, and nasal accessory sinuses, together with a more concise account of the indications, complications, and after-treatment of each operation. In this the authors have succeeded admirably, and the book is one which will be of interest and assistance to anyone about to undertake the operations described in it. Only one operative method is usually discussed at length in each case, although other procedures are often mentioned and arguments given for or against their adoption. Prof. Moure has such a great reputation that his opinions on such matters must command the respect and interest of laryngologists in this country. The lavish illustrations are a noteworthy feature of the book, especially the drawings by S. Dupret, which are mostly full-page and fully life-size, and which depict each stage of the major operations. The operation of lateral rhinotomy, especially associated here with the name of Prof. Moure, is very fully detailed and illustrated; indeed, it is described twice over in different chapters, and some 10 or 12 full-page illustrations are printed twice in almost identical form. Two variations of this method of obtaining access to the nasal passages are given, and Prof. Moure rightly insists that they are distinct operations; the first, called "ethmoidectomy," includes removal of the nasal process of the frontal bone and gives access to the roof of the nose and the sphenoidal region; while the trans-maxillo-nasal operation opens the antrum and also gives access to the nasopharynx.

Although the work deals largely with these and other major operations, minor procedures, such as cauterisation and the treatment of epistaxis, receive attention, and it is in such lesser matters especially that the methods recommended differ in some particulars from the practice in general vogue in England. Local anæsthesia is recommended for operations up to, and including, those of the magnitude of the Caldwell-Luc operation; and it is described, though not definitely preferred, for the frontal sinus operation and even for lateral rhinotomy. For the removal of adenoids no anæsthetic, local or general, is the rule; and the authors feel so strongly on this point that they say that "for some years a tendency has shown itself in favour of general anæsthesia with chloroform, and certain operators, following in this a bad foreign influence, have made a regular surgical intervention of the removal of adenoids." Other points of interest may be mentioned. Cauterisation of the inferior turbinals, to reduce hypertrophic swelling, is condemned, as the effect only lasts for a few months, and vibro-massage of the mucous membrane is preferred. Prof. Moure still removes septal spurs with his spoke-shave; and he does not consider a traumatic or irregular septal deviation suitable for submucous resection, but prefers to cut away the convexity with its muco-perichondrium, leaving only the mucosa on the concave side. For chronic antral suppuration he employs the Caldwell-Luc operation, and considers the intranasal route insufficient; he curettes away all the antral mucosa, sews up the gingival incision, and packs antrum and nose with a long strip of gauze which is only completely removed by the end of six or eight days. For frontal sinusitis he condemns both the intranasal operation and removal of the anterior wall, and claims that he has proved that the frontal sinus, thoroughly curetted, is obliterated during healing; he performs the Ogston-Luc operation and sutures the external wound completely, leaving a long strip of gauze in the sinus to be gradually removed through the nose.

Although certain of these methods will not meet with general approval, the book is a most valuable and instructive one.

Die Funktionsprüfung des Akustischen und Statischen Labyrinths. By Dr. MAXIMILIAN RAUCH, Assistant to the University Clinic for Diseases of the Ear, Nose, and Larynx. Vienna and Berlin: Julius Springer. 1924. Pp. 71. $0·60.

IN this little book Dr. Rauch has, at the request of his pupils, put together and expanded a series of articles on examination of the vestibular apparatus which he wrote in 1912. To this he has added a preliminary section on the functional testing of hearing, which provides an adequate description of all the usual tests. The examination of the static labyrinth is, however, a much more complicated matter, and it is extremely difficult for the student to memorise accurately the different directions of the nystagmus which results from stimulation of each semicircular canal by mechanical rotation and by caloric stimulation. The nystagmus is the direct result of movement of the endolymph in the canals, and consists in a slow component due to this movement and a rapid component due to cerebral correction; the fundamental rule, from which the direction of the nystagmus can be deduced, is that the slow movement of the eyes is in the same direction as the movement of the endolymph. Dr. Rauch has set out the methods of testing and the reactions in considerable detail, aided by photographs of a large-scale model of the membranous labyrinths, and with sufficient clarity to be of great help to those studying this intricate subject; it is unfortunate that, by a misprint, the right labyrinth is named the left, and vice versâ, in one of the illustrations.

BOOKS FOR NURSES.

Practical Nursing. Sixth edition. By H. E. CUFF, M.D., F.R.C.S., and W. T. GORDON PUGH, M.D., B.S. London: William Blackwood and Sons. 1924. Pp. 635. 10*s.* 6*d.*

Dr. Gordon Pugh has brought up to date a book already popular with the nursing profession, which in its original edition formed the foundation of much theoretical instruction in a great many of the leading training schools. The subjects dealt with in the latest edition cover the curriculum of training in nursing, hygiene, and dietetics required by the General Nursing Council, and the book supplies a comprehensive text-book for all nurses wishing to qualify for the State Register. The chapter on hygiene gives evidence of the growing demand that the trained nurse shall comprehend the underlying principles of public health, and that these principles should form part of her hospital training. Excellent chapters on fevers and fever nursing, the nursing and feeding of sick children, and diseases of the nervous system should prove helpful to nurses working in special hospitals who may wish to qualify for one or more of the supplementary parts of the State Register.

A Manual of Nursing Procedures. By E. PRISCILLA REID, R.N., MABEL HOFFMAN, R.N., HAZEL JENNINGS, R.N., and LILLIAN A. READ, R.N. London and Philadelphia: W. B. Saunders Company. 1924. Pp. 181. 8*s.* 6*d.*

THIS book sets out the nursing procedures in the American hospitals with which the authors are specially acquainted, and should prove of value to nurses trained at those schools and elsewhere. It should also prove useful to probationers preparing for examinations. The text is concise, and tabulated under headings which include the purposes, the required equipment, the method of procedure, and the necessary precautions of the carrying out of several nursing duties, the object of adopting this form being to save confusion, time, and energy. Excellent illustrations elucidate the text and emphasise correct nursing technique.

Belle Vue School of Nursing. By DOROTHY DIX HILL. New York: The Macmillan Company. Pp. 187.

Miss Hill has arranged concisely a tabulated list of recipes based on the nursing procedures adopted at Belle Vue School of Nursing, New York. The chapter on bandaging is undoubtedly the best contribution in the book, although one would question the advisability of pupil nurses being taught to fasten a bandage with a " pin " as an alternative to fastening it with a safety-pin. The book may prove of value to the pupil nurses at Belle Vue, but as the underlying principles of nursing are only dealt with in a very limited sense it cannot be considered a substantial addition to nursing literature.

Maternity Nursing in a Nutshell. By ELIZABETH H. WICKHAM, R.N., Former Supervisor of the Maternity Department, Lebanon Hospital, N.Y. Philadelphia: F. A. Davis and Co. 1924. Pp. 167. $1·50.

THIS little manual will probably be of service to graduate nurses in America who are not midwives and have only a limited knowledge of maternity nursing. The British nurse may be interested in it as illustrating American methods, but as most of them who do maternity nursing are midwives they will find the book too slight and sketchy to be of service. In dealing with the emergency treatment of post-partum hæmorrhage, Miss Wickham gives the usual measures—massage, ergot, posture, hot vaginal douche (124° Fahr.!), but adds that if these fail the nurse should "as speedily as possible proceed to pack the uterus." This is a difficult operation at any time, and certainly not one to be adopted by a nurse. No mention is made of bi-manual compression or intramuscular injections of pituitary extract. Miss Wickham gives her views on "twilight sleep," but omits to lay stress on points to be observed by the nurse in such cases. Shell-fish is advised when breast milk is deficient; the author believes that such food increases the supply of milk when all other foods fail. There are a glossary, appendix, index, and a good supply of illustrations to this little book.

NOUVEAU TRAITÉ DE MÉDECINE.

Edited by G. H. ROGER, F. WIDAL, and P. G. TEISSIER. Vol. VIII.: Pathologie des glandes endocrines; troubles du développement. Paris: Masson et Cie. Pp. 455. Fr.40.

WE have previously had occasion to remark on the excellence of this system of medicine. The present volume maintains, in many respects, the high standard of its predecessors. The articles on diseases of the pituitary and thyroid glands, especially those by G. A. Sézary and A. Souques, are models of precise reasoning, and the numerous illustrations with which the whole volume is embellished form a clinical collection of great interest. The section on the pathology of the suprarenal glands is marred by the over-emphasis laid on the supposed syndrome of hyperfunction of those organs. Without questioning the possible occurrence of this syndrome on the existing evidence, there are no grounds for dogmatic statement, and this article departs from that spirit of critical examination which should be present always in systematic medicine.

Reports and Analytical Records.

"TABLOID" PARATHYROID.

(Burroughs, Wellcome and Co., Snow Hill Buildings, London, E.C. 1.)

Tabloids prepared from pure gland substance enable the clinician to make use of the action of parathyroid in regulating the calcium metabolism of the body. The use of parathyroid in many and diverse pathological conditions is now well supported by medical evidence, and this preparation has been made by trained workers and has undergone close inspection to ensure the genuineness of the product. Each "tabloid" product represents two-fifths of a grain of fresh gland, equivalent to one-tenth of a grain of desiccated gland substance. "Tabloid" Parathyroid Gland is issued in bottles of 25.

"OSMO" KAOLIN (MORSON).

(Allen and Hanburys, Ltd., Plough-court, Lombard-street, London, E.C. 3.)

Kaolin, or aluminium silicate, has proved useful in medicine mainly because of its important quality of adsorption, but it is, of course, necessary that its purity should be unquestioned. "Osmo" Kaolin (Morson) is a pure colloidal preparation presenting kaolin in an exceedingly fine state of subdivision secured by a special process of preparation. Its use is indicated in intestinal stasis and its sequelæ, and generally where alimentary toxæmia is present, while it has proved helpful, according to many observers, in dysentery and diarrhœa. Externally as a cataplasma to remove œdema and to relieve the pain and swelling of inflammation it has been successfully employed. The preparation is supplied in 8 oz. cartons.

TETRAFORM.

(British Drug Houses, Ltd., 16–30, Graham-street, City-road, London, N. 1.)

Carbonis tetrachloridum has been used as an inhalant in the relief of hay fever, as an anodyne for neuralgic pains, and as an anthelmintic, especially in the treatment of hook-worm disease in America. In any case the purity of the drug is essential, as impurities such as carbon bisulphide and phosgene are excessively toxic. The British Drug Houses, Ltd., have put upon the market a preparation, Tetraform, which is guaranteed to be free from these and other poisonous substances. The standard of purity which Tetraform is guaranteed to comply with is set out by the B.D.H. firm as follows:—

> "It gives no reaction to the alkali plumbite test for sulphur compounds, including carbon bisulphide, thus indicating the absence of these toxic impurities; it contains no free acid, no chloride, and no free chlorine; it yields no appreciable residue on evaporation; and it gives no reaction to the potassium test for organic matter and aldehydes."

It is claimed to be a perfectly safe remedy in the treatment of ankylostomiasis and other intestinal diseases due to parasites, the doses and age modifications being carefully observed, but its exact action as an anthelmintic is not quite certain.

GLAX-OVO.

(Glaxo House, 56, Osnaburgh-street, London, N.W. 1.)

This new dietetic preparation consists of the solids of milk combined with malt flour, cocoa, sugar, and an antirachitic extract of cod-liver oil in a highly concentrated form. The percentage composition of essential foodstuffs is stated as:—

Moisture ..	2·5	Carbohydrate ..	62·2
Fat	13·3	Ash	3·7
Protein	18·3		

Cane sugar is present to the extent of 18 per cent. and cocoa (containing 22 per cent. cocoa butter) to the extent of 6 per cent. In respect of that factor in which cod-liver oil is peculiarly rich—namely, the factor controlling calcium metabolism—a marked degree of success is claimed, for it appears to have been concentrated no less than 2000 times. Glax-ovo is supplied in the form of a powder contained in air-tight tins, and needs the addition of boiling water only to prepare a beverage with the distinct flavour of chocolate. It provides a means of obtaining the benefit of cod-liver oil without its unpleasant qualities of flavour and repetition.

UBANA.

(Ubana Shokai, 83, Ebury-street, London, S.W. 1.)

This is a crude native sulphur said to be a hot-spring concentrate imported from Japan. When analysed it was found to have the composition:—

	Per cent.
Sulphur	68·9
Moisture	1·5
Acidity (as sulphuric acid)	0·8
Inert matter of a siliceous character	28·8
Iron	trace.

The sulphur is intended for use in a hot bath, two handfuls of the preparation mixed in a bath being sufficient for all purposes, the body remaining immersed for 15–20 minutes. For local application the affected parts may be bathed with a solution of the same strength. Directions are given for the use of Ubana internally in digestive disorders. Apart from its application in diseases of the skin, sulphur has been recommended for neuritis, gout, and some forms of rheumatism.

PRUNOL OR PRUNE JELLY.

(Prunol, Ltd., 4, Pickering-place, No. 3, St. James's-street, S.W. 1.)

Prunol is a preparation of prunes, Demerara sugar, senna, and ginger, things in this or a similar combination well known for their laxative properties. It is a safe remedy for children and has proved useful not only in constipation but as a mild purgative in inflammatory conditions. Where easy and regular motion is desired, the average dose for an adult is one full teaspoonful to be taken when retiring at night, while for children of from 4 to 6 years of age a smaller dose is sufficient.

"KRAFT" CANADIAN PASTEURISED CHEESE.

We have received from Colonial Produce Publicity (47 and 48, Berners-street, London, W. 1) a sample of a cheese prepared by the "Kraft" process of pasteurisation which kills the gas-producing bacillus and enables a rindless cheese to be placed on the market. Cured cheese is blended to taste with fresh cheese, both in finely-divided form, and the blend is placed in a steam-jacketed kettle, containing an agitator, until the product is reduced to about the consistency of soft putty. It is then transferred hot to boxes, previously lined with tinfoil, the cover of which, when nailed on, acts as a press. The envelope obviates the cheese being exposed to dirt or harm, and is a protection against mould, evaporation, and shrinkage. We can testify to the product being both palatable and digestible. It is highly desirable for such a staple foodstuff as cheese to be delivered to the customer in a sealed packet, and the "Kraft" pasteurised cheese is everything that a cheese should be.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 27, 1924.

EDUCATION IN HEALTH.[1]

FROM his office window at the Ministry of Health the Chief Medical Officer looks down on the flow of humanity in the street outside and observes how far the available knowledge of hygiene has penetrated into the everyday life of the people. In some respects the change has been rapid. Where, a hundred years ago, intemperance was the Englishman's besetting fault, gross and widespread drunkenness has almost disappeared. Fifty years ago a commercial firm was able to announce itself as bug destroyer "for the upper classes only," without there being any obvious absurdity in the existence of enough bodily parasites in such circles to make good business. Twenty-five years ago the tight clothing and trailing skirts of women were part of a manner of life which produced a form of anæmia so common as to constitute a considerable part of out-patient material at our hospitals. The prevailing fashion in dress along with more active amusements and the open-air habit have made chlorosis as rare or perhaps rarer than pernicious anæmia. But still, as Sir GEORGE NEWMAN reminds us, people suffering from colds sneeze and cough into each other's faces; too many people live in overheated, ill-ventilated, and stuffy rooms, on leaving which for the less sheltered streets they fall victims to bronchitis and pneumonia; many valuable and cheap foods are almost entirely neglected. The public is unaware that milk, butter, vegetables, fruit, and other foods are preserved, coloured, or adorned with substances which may not be harmless. They have not learned to regard tuberculosis as the result of personal infection or of drinking tuberculous milk, or they would have put these beliefs into effective application. Sound practice lags behind the ascertaining of truth, and Sir GEORGE NEWMAN laments the fact that the enlightenment of the public has not kept pace with the progress of science. Mental hygiene, that most fruitful field for popular health education, is as yet almost untouched; life might be prolonged, its capacity and value enhanced out of measure by periodic medical examination, willingness to accept advice on health maintenance, and diligence to learn the laws of hygiene.

Everyone agrees that public education in health must begin early. What form, Sir GEORGE NEWMAN asks, should the teaching of hygiene take in the elementary schools? On the one hand, the child can be given information respecting the theory of hygiene, or on the other he may be taught by practice to form certain habits. By universal consent the child is just handed a toothbrush and told to clean his teeth. He learns these things because they are accepted as a daily routine. In America they are made a form of kindergarten play. If only Mr. NEVIL MASKELYNE, whose death we deplore, had incorporated some health tricks in his programme countless children would have learned them for life at one visit. Practice is vastly more cogent than precept. At a recent meeting of the Dumbartonshire Education Authority a suggestion that teachers should give special short health talks to pupils was met by the riposte that the Education Authority itself required health talks on the subject of issuing to the children in their schools filthy and dilapidated books. The gloom and grime of many elementary schools further south than Dumbarton, and the condition of their lavatory accommodation, are such as to set a low standard of cleanliness in the minds of many school-children which no amount of precept can subsequently alter. It is for this reason that the school medical service has within it the germ of vastly potent hygienic education. It was only in 1907 that the system of medical inspection and treatment of school-children was established by Act of Parliament, and we can still recall the consternation aroused in 1908 when Dr. JAMES KERR, who has just retired from his great office under the London County Council, gave out that at least 90,000 children in the London schools were urgently requiring medical treatment. Things are changed to-day, when not only do children obtain medical treatment in London as a matter of course, but the school is the acknowledged centre for the control and prevention of disease, and the school medical service the proven means of increasing the health and strength of the population and of diminishing the mortality-rate. The influence of this service has percolated into the life of the whole country, and its principles have even penetrated the public schools.

Health methods will not be accepted by the people of this country if they are foisted upon them against their will. Nevertheless, as we learn[2] from Mr. T. B. PARTINGTON, two years' experience has shown the cinema to be a new force in fighting venereal disease; night after night he has demonstrated in packed halls seating 2000–3000 Lancashire men and women. They were there out of curiosity, you might say. Mr. PARTINGTON meets this objection by recalling the loud applause, given as only northerners can give it, as he pleaded for a higher moral standard for the stamping out of venereal disease in the large manufacturing towns of Lancashire, where a week's campaign resulted in a remarkable increase in the attendance at the venereal disease clinic. The holding of propaganda weeks of various sorts has in many parts of the country taken effective hold of public opinion, whether under the name of Baby Week, Health Week, or Rat Week. Of the written word, the annual report of the medical officer of health is a form of propaganda work of which insufficient use is made; such reports afford opportunity and scope to guide the public in the directions of advance appropriate for the locality. The first and best form of hygienic education is the effective administration of the public health, including medical services. With the possible exception of Leicestershire, the insurance committees, which were entrusted by the Act of 1911 with the duty of giving lectures and publishing information on questions relating to health, have failed to make this provision. They may have realised from the first that the bulk of their educational work could only be performed effectively by the insurance practitioner himself in the ordinary discharge of his duty. On the direct methods for providing supplementary teaching over and above these well-authorised channels, Sir GEORGE NEWMAN makes hints and suggestions which are set down at length on another page. The potentialities for public health teaching of the cinema and of the wireless can hardly yet be properly assessed, but they are evidently boundless.

TUBERCULOSIS IN THE SERVICES.

The report on the health of the army for the year 1921, just issued as a Blue-book (H.M. Stationery Office. Price 3*s.*), is the first to be presented by Sir William Leishman, who explains its delayed appearance by the many changes involved in the gradual reversion to a peace footing. It contains much of interest to which we shall return. We have now seen the reports for this year from all three of the fighting services, and have extracted from them the figures given for tuberculosis. It is a little surprising to note that in none of the reports is any special consideration given to these figures, Eighty years ago 89 men died of tuberculosis among the 5000 Foot Guards, a rate of 17·6 per 1000; of hospital admissions from another unit, 236 out of 286 died; and the terrible prevalence of tuberculosis in the army seems to have been the agent which first compelled thought for hygiene in that service. Now, although relatively few deaths are ascribed to tuberculosis as compared with some diseases such as malaria and pneumonia, the total loss to the services is still great. In 1921 it amounted to 721 fighting men. Some instruction may be gained by comparing the prevalence of pulmonary tubercle with that of pneumonia, tonsillitis, and bronchitis in the various military areas. Arranging these in order, beginning with London and the Northern Command, where tubercle is heaviest, downwards to Ireland, where it is least, it will be apparent that pneumonia stands in no relation to tubercle, although in the United Kingdom bronchitis and tonsillitis vary to some extent with it. For stations abroad there appears to be no similarity whatever between the curves. The question arises: Why has Ireland in 1921, with 50,531 men employed there, in circumstances, the report says, of hardship, lower rates than any other Command in the United Kingdom for pulmonary tubercle, tonsillitis, pneumonia, and the second lowest rate for bronchitis? A possible explanation is the want of association, at that time very definite, between troops and civil population. More recent figures may give the clue. In 1921, in the United Kingdom, the highest pulmonary tubercle-rate was 3·1, in London and the Northern Command; the maximum for pneumonia was 6·3, in the Western Command; for bronchitis 48·0, in the Northern Command, already mentioned with the maximum for pulmonary tubercle. London has the highest rate, 62·8, for tonsillitis. These relations deserve further study.

Tubercle (Pulmonary and Other) in the Fighting Services during 1921.

◆

SPONTANEOUS AND EXPERIMENTAL ENCEPHALITIS IN RABBITS.

The experimental transmission to animals of epidemic encephalitis and other affections of the central nervous system forms the subject of a critical review by Dr. C. Da Fano in the August number of *Medical Science*. Our knowledge of the so-called spontaneous encephalitis of rabbits dates only from 1922, though its occurrence had been suspected by C. B. Bull since 1917. It has now been ascertained that it affects not only rabbits but also mice, and that it occasionally manifests itself in the shape of circumscribed epizoötics. It is more diffuse in certain countries, notably America, than in others, and does not, as a rule, give rise to symptoms. These may, however, be present, particularly when the disease occurs epidemically or if the rabbits are used for experimental procedures on their central nervous system. The onset is usually insidious and the first indication of any trouble is the wasting of the animals. The temperature is at times subnormal, though fever has occasionally been observed. The hair falls out in patches and there is some discharge from the eyes. As the disease progresses emaciation becomes profound and muscular weakness and convulsions occur. Some authors noted persistent drowsiness, followed in most cases by tremor shortly before the development of paralysis which may be slight or marked, general or localised. In such cases the mortality is high, though the animals can survive several days and even recover. Death may supervene during a convulsion, which is sometimes preceded by coma, or takes place in coma.

Histologically, the disease is characterised by small-celled infiltrations, nodular cell aggregations, and focal necrotic areas associated with a variable degree of nerve-cell degeneration. The infiltrations can be meningeal, peri-vascular, subependymal, and parenchymatous and differ greatly in intensity in different animals; they consist of lymphocytes and some plasma cells, while polymorphocytes are, as a rule, absent. The nodular cell aggregations also consist of mononuclear elements of the lymphocytic type, and may be so large as to be visible to the naked eye in stained specimens. The necrotic foci are generally formed of a definitely necrotic centre surrounded by an inner ring of epithelioid cells and an outer layer of mononuclear elements. The malady is probably related to a form of spontaneous nephritis, investigated in 1919 by E. T. Bell and T. B. Hartzell; it is transmissible from animal to animal by cage infection and by intracerebral inoculation of sedimented urine and brain or cord emulsions from sick rabbits, and has been shown to be due to a protozoon-like parasite which according to some authors is a microsporidium belonging to the sporozoa. The parasite has been detected in the brain and kidney lesion of affected rabbits and mice, but its life-cycle is, so far, unknown. Dr. Da Fano suggests that the unsuspected occurrence of this affection has misled various authors in their attempts at transmitting to rabbits syphilis, general paralysis of the insane, and epidemic encephalitis, in so far as they describe symptoms and histo-pathological lesions which he considers characteristic of the spontaneous parasitic disease. Similarly Lucke's observation of spontaneous encephalitic lesions in monkeys is held by the reviewer to invalidate the few recorded instances of presumed transmission of the epidemic disease to those animals.

The last ten pages of the review are devoted to a discussion of the interlaced questions of the herpetic and encephalitic viruses. It is now established that the vesicular fluid of all forms of herpes, other than idiopathic herpes zoster, contains a virus which, when inoculated into rabbits and other domestic animals, gives rise to a meningo-encephalitis or a meningo-encephalomyelitis with involvement of certain cranial, spinal, or even sympathetic ganglia. This experimental disease is generally characterised by a certain incubation period, a peculiar symptomatology, transmissibility in series, and sufficiently characteristic inflammatory and degenerative lesions. It is, in the main, easily distinguished from the parasitic form. The herpes virus is endowed with biological properties which may now and then undergo certain variations and is probably more diffuse than has hitherto been suspected; it has been occasionally found in the saliva, nasopharynx, cerebro-spinal fluid, blood, and even fæces not only of subjects exhibiting skin lesions, but also of apparently healthy carriers.

LEVADITI and other workers have succeeded in isolating from the brain substance, nasopharynx, and cerebrospinal fluid of cases of epidemic encephalitis a limited number of so-called encephalitic viruses. However, when inoculated into rabbits and other laboratory animals, these viruses give rise to a transmissible disease which is clinically and histo-pathologically identical with that due to the herpes virus, and the so-called encephalitic viruses are indistinguishable from herpetic strains by available biological tests. It is, therefore, possible that the so-called encephalitic viruses are in fact only herpetic strains found by chance in the material employed for experimental transmission, and that they may have nothing in common with the ætiological agent of epidemic encephalitis. It would thus appear to be still uncertain whether the unequivocal transmission of epidemic encephalitis to animals has as yet, after all, been achieved; if this should prove to be so its ætiology would have to be investigated anew.

Annotations.

"Ne quid nimis."

THE INDEX GENERALIS.

THE ideal personal reference book for the medical seeker is yet to find. Even the "Medical Register," whose alphabetical arrangement and official accuracy make it so satisfying, suffers from the disability, which we understand can only be removed by Act of Parliament, of containing two smaller alphabetical lists at the end where they may readily be overlooked; and the value of the "Medical Directory," as a more detailed fount of accurate information, is seriously depreciated by the disappearance of the asterisk which implied that entries had been revised to date. All other lists of reference suffer more or less from the varying estimate of who's who and what's what. On a more universal scale, the year-book familiarly known as "Minerva," when first issued in 1891 from the publishing house of K. J. Trübner, in Strasbourg, possessed practically a monopoly as a guide to the learned world. The twenty-third edition appeared at Strasbourg in 1914, the twenty-fifth edition in much diminished form in 1921 as a publication of the Union of Scientific Publishers of Berlin and Leipzig. The basis of "Minerva" is, of course, the German tongue, although the names of institutions are generally given in the language of the particular country. A serious competitor to "Minerva" has now appeared in a handsome English edition of the "Index Generalis," described as the year-book of the universities, libraries, astronomical observatories, museums, scientific institutes, academies, learned societies,[1] of which the French edition came out in 1919 as a thin paper-covered volume. Mr. H. J. Waring who, as Vice-Chancellor of the University of London, commends it to the attention of the scholar, the administrator and all concerned in the development of higher education, indicates in a preface what such an enterprise entails upon editor and publisher. The Index contains more than 6400 separate entries, for the most part in the language of the source from which it arose, except for a few countries of minor importance which are given in French. Technical terms have been avoided as far as possible, but, for such as are used, a short vocabulary is given at the end of the book. An alphabetical list of more than 70,000 names enables the reader to locate anyone who comes within the scope of the book, and the indexer has been kind in indicating whereabouts on the page the name appears. It would be easy to carp at a host of minor inaccuracies or at the coarse yellow paper and rather unattractive type used by the Bordeaux printer. It is also annoying to find the first few sections of the book separately numbered under topographical headings; thus, the British Empire has 165 pages, followed by the United States with 160 pages and by France with 169 pages, a number of advertisements being insinuated as "buffer states." But no one who has frequently felt the want of such a book can fail to be grateful to the editor and the publisher for a work of eminent value and one that will spare the honest seeker hours of fruitless search. We commend the book most cordially wherever it is necessary to identify the learned people of all nations and countries, and desire for it the wide circulation which will enable the publishers cheerfully to bring it up to date year by year and to ensure its substantial accuracy.

PROFESSIONAL PITFALLS.

A STUDY of the annual report of one or other of the great medical protection associations is always a matter of interest to the practitioner in that it brings a realisation, perhaps for the first time, of some of the pitfalls in the rough road of professional life which he *may have been so far lucky enough to escape.* We have on previous occasions in these columns urged the importance to all medical men of ensuring adequate professional protection for themselves, and the report of the Medical Defence Union for the year 1923–24 shows a steady and healthy increase in the number of members, which in July, 1924, amounted to 11,550. The Council of the Union states that the number of cases with which it dealt has increased and that there is reason to believe that charges against medical practitioners are becoming more frequent, possibly because certain actions lately heard in the High Court have encouraged patients to seek to obtain damages from their medical attendants when recovery has been more prolonged or less complete than they imagine it should have been. Members of the Union have been advised by the Council on a variety of subjects which extend alphabetically from Acts of Parliament to X ray burns, including such matters as debt collecting, door plates, herbalists, and housing difficulties. Up to the end of 1923, 76 cases were placed in the hands of the Union's solicitors. Of these cases, 9 were concerned with libel or slander, 25 with malpraxis, 8 with prosecution of unqualified persons, and 34 with arbitration and personal matters. It is noteworthy that actions in which a charge of malpraxis or negligence is raised are greatly in the majority, while there is a marked falling off in actions for libel and slander; and it is also of interest to note that the number of unqualified practitioners for the supervision of whom action has been taken has remained fairly constant since 1909. This branch of the Union's work is one that is generally recognised as being of extreme importance not only to the medical profession but to the public at large. But this figure does not represent the total number of cases that were investigated by the Council in which no legal action could be taken, as bogus medical practitioners for the most part are fully alive to the significance of the penal clause of the Medical Acts, which prohibits the wilful and false assumption of title only and not unqualified practice, and thus manage to remain just within the law while imposing on the public. Unfortunately, there is no immediate prospect that any alteration of the law in this respect will be obtained. A marked decrease in the number of prosecutions for libel against medical men, which has fallen from 31 in 1919 to 9 in 1923, may be interpreted as an indication of the widespread recognition of the power of the Union.

The solicitors give details of a few cases which cannot fail to be instructive and illuminating. The first quoted deals with the action which was conducted on behalf of a member of the Union against several officials of a miners' lodge who had circulated a pamphlet amongst the other members of the lodge to the effect that the medical man was incompetent and biased against the workmen in his capacity as a medical referee under the Workmen's

Insurance Act. After a protracted hearing the case resulted in a verdict for the medical man, with £100 damages. Such a case as this will help to improve the position of medical men practising among miners. Reference is again made to the extreme importance of securing an X ray photograph in a case of suspected fracture or dislocation. This we referred to in a similar connexion some months ago,[1] and is emphasised in a clinical note which appears on p. 649. During the year the solicitors were consulted on several occasions by medical men holding public offices where the attempt was made by the public authorities under whom they were employed to reduce their salary, and it was pointed out that where a contract provides for the employment of an official at a fixed salary, that salary cannot be reduced save by mutual consent, and the only way of enforcing reduction is by termination of the existing contract and the creation of a fresh contract at a reduced salary. This view, the solicitors state, has now been adopted by the Ministry of Health. A word of advice on the conduct of any case is always valuable, and the solicitors make a special appeal to medical men consulting them that a full statement of the facts bearing on the case directly or indirectly should be made, and they add: "Members of the medical profession will appreciate that the correct diagnosis and treatment of a case may depend on details or symptoms which appear to the layman to be insignificant and to have no bearing. This is equally true of legal matters." An interesting case is reported where a complaint was made against a medical man of employing a woman to attend childbirth who was not certified under the Midwives Act of 1892. The solicitors warn medical men to be on their guard against the presence of unqualified midwives at any obstetrical case. Such women are liable to make use of doctors to cover them in their practices. Medical men by virtue of their calling are practically under obligation to attend any case of emergency, but when they are called in by an uncertified midwife they run a considerable risk if they sign a certificate to enable the mother to obtain maternity benefits under the National Health Insurance Acts. It is wise for physicians, if they receive a series of these emergency calls from uncertified women, to make it strictly clear either that they will not respond to any future calls or if they do respond that the woman in question must at once leave the case.

As an instance of a liability which may be unwittingly incurred in connexion with the sale of a practice by a medical man, the following case is worthy of quotation in some detail. The solicitors state:

> A member of the Union inserted an advertisement in the medical press notifying his intention to dispose of his practice and inviting purchasers to communicate direct with him. He advisedly did not consult agents, as he preferred to effect a sale without their intervention. That this practice was for sale came to the knowledge of a certain firm of medical transfer agents, who wrote the member informing him that they were sending down certain possible purchasers. The member did not acknowledge this letter in any way, though he saw the gentlemen who were sent by this firm, but he did not come to terms with them. Subsequently, another would-be purchaser came down, who was sent by these agents, which fact was never communicated to the member. Eventually, this gentleman purchased and the agents put forward a claim that the sale had been effected through their instrumentality. We were thereupon consulted by the member. The fact that the member had seen the original would-be purchasers sent down by these agents without informing them that he refused to deal with them in any way, in our opinion, was tantamount to accepting their services, and we thought that in the circumstances the Court would recognise their claim. We are glad to say, however, that we were able to induce the agents to accept a reduced fee.

If medical men avail themselves of the assistance of medical transfer agents, even though such assistance is volunteered and not invited, they may make themselves liable for the services thus rendered, and it is therefore advisable to refuse this assistance at once if it is not desired.

The benefits of the Union have been increased in two important directions. The first is geographical, in that membership is now extended to medical practitioners practising in the Irish Free State, Northern Ireland, the Channel Islands, and the Isle of Man; the second is financial, as from May 1st, 1924, the indemnity against damages and costs of the other side is unlimited. This latter extension is the outcome of the alarm caused in the profession by the damages originally imposed by the High Court in the Harnett case, and the policy of unlimited indemnity has been adopted both by the Medical Defence Union and the London and Counties Medical Protection Society. The solicitors' report ends with a tribute to the esprit de corps among members of the sister profession of medicine, which it would, perhaps, hardly be seemly to quote in these columns.

EDUCATIONAL FACILITIES FOR MENTALLY DEFECTIVE CHILDREN.

THE problem of the mentally defective child is one with which sociologists have of late been much concerned, as the discovery that such children may be the pupal stage of certain social parasites—the unemployables—is of recent date. Yet there is evidence to show that thoughtful and adequate educative measures adopted towards these unfortunate children can make them in many cases worthy members, however humble, of the community. The Board of Education have for some time had under consideration the position of mentally defective children in the country generally, and they have recently issued a Circular (No. 1341) to the local education authorities, inviting coöperation in doing all that is possible under existing circumstances to ameliorate the lot of such children. At the moment it is impossible to make fully adequate provision for this work, owing to defects in obtaining suitable accommodation and funds, but, the Board points out, much can be done, even under present conditions, towards realising the aims of the Mental Deficiency Act of 1913 and the Elementary Education (Defective and Epileptic Children) Act of 1914. The first duty devolving on the local education authority is to make a thorough ascertainment of all mentally deficient children in their area who will thereby fall into two classes: first, those who ought to be notified forthwith to the Mental Deficiency Committee, and second, those who ought to be sent to special schools. Legal responsibility for the first class ceases as far as the local authority is concerned on notification. The second class, the important one, is further subdivided at present of necessity into two groups—namely, those for whom special school accommodation is available, and those who, in the absence of such provision, must either attend the public elementary schools or stay at home. Children in the special schools are supervised, under the Act, up to the age of 16, when they are either discharged as fit members of society, or, if need be, notified to the Mental Deficiency Committee and placed in institutions or under guardianship. Where no special school exists supervisory arrangements can be exercised through school nurses, care committees, paid welfare workers, or voluntary organisations, towards the cost of which the Board are prepared to furnish reasonable grants. At the age of 16 the mentally deficient child passes out of the sphere of the local authority, and it is at this point that a most serious gap exists in the educative machinery, as notification of appropriate cases to the Mental Deficiency Committee is often overlooked. The Board emphasises most earnestly the duty of the local authority in passing under review periodically all mentally defective children under the age of 16 in order that this gap may be bridged, and that the children may not be lost in the general population only to be rediscovered by the Mental Deficiency Committee or the police when from lack of supervision and help they have got into trouble and may have done serious damage both to themselves and to the community. The problem of the child who does not require to be notified is not ended when he or she is passed out from the special school or its equivalent at the age of 16; employment must be secured and useful citizenship assured. Further supervision by an "after-care" association is of the utmost value. In Birmingham, the Special Schools After-care Subcommittee has been in existence since 1910. Its duties include keeping a record of the subsequent histories of former pupils of the special schools in the city and assisting them to find employment. The total number of former pupils in work has risen owing to the enhanced demand for labour in Birmingham in the past year, and 37 per cent. are shown to be earning wages as compared with 35 per cent. in 1922. In view of the allegations so often made that all criminals are mentally defective, it is interesting to note that an examination of the records of the Committee extending over a period of 21 years and relating to more than 3000 defectives shows that, except for certain cases of immoral conduct and others of petty thieving, criminal offences have been few. The work done by this Committee is of inestimable value not only to the individual concerned but to the community.

ENERVATION OF THE KIDNEY.

PERIARTERIAL sympathectomy of the large vessels of the extremities is, owing to the strenuous advocacy of Leriche, undergoing a somewhat extensive trial, though as yet it is too soon to speak with any confidence of the ultimate place which the operation will assume amongst surgical procedures. E. Papin[1] was the first to suggest and carry out a similar operation for certain affections of the kidney. A study of the subject has been made by P. Flandrin[2] in Prof. Legueu's clinic. The sympathetic nerves for the kidney come off the semilunar ganglia and run a more or less regular course along the upper and posterior aspects of the renal artery, so that a decortication of that vessel will cut off all nerves running to the kidney. The operation upon the renal hilum may be comparatively simple if there is a single renal artery and if the pedicle can be approached at some distance from the kidney itself. But should the kidney not admit of delivery to the surface, or should there be an accessory renal artery, the procedure may become technically very difficult of accomplishment, and, apparently, there is a danger in the attempt of doing such damage to the renal veins that nephrectomy becomes the only outlet from a surgically embarrassing situation. The operation has been performed mainly for two conditions, nephralgia without discoverable lesion, and those cases of early hydronephrosis dependent upon a narrowing at the uretero-pelvic junction in which a plastic procedure or nephrectomy seems scarcely justifiable. As applied to the latter condition it will be most interesting to watch results which already bid fair to prove satisfactory. C. A. Pannett[3] considers that one group of these cases of hydronephrosis depends upon a reflex spasm set up at the uretero-pelvic junction, perhaps associated with a polyuria, and that in another group polyuria alone may cause a distension of the renal pelvis if it be associated with a congenital narrowing of the renal excretory duct at this particular point. It is possible that both the reflex spasm and the rate of renal secretion might be altered as the result of cutting off the kidney from its connexion with the central nervous system. Flandrin has studied the changes in urinary secretion as a result of enervation of the kidney. On the whole, he reports no changes in the urine after the immediate effect of the operation has worn off, but in two cases the secretion of urine was much interfered with. In these two patients the section of the renal nerves was particularly easy and certainly complete. He suggests that, perhaps, in the earlier operations, before facility in technique had been gained, a total enervation was not achieved and the good results depended upon the incompleteness of the operation. As to the subjective results to the patients, there has been uniformly an improvement. The lumbar pain has disappeared and the renal crises have been absent in all the small series of cases reported upon. These observations are exceedingly interesting and worthy of further study.

VETERINARY OBSERVATION.

AT the opening of the Conference of the National Veterinary Association, which met recently in Aberdeen, the chairman appositely referred to the veterinary profession as the one, par excellence, in which observation was required. It was Prof. F. M. Caird, of Edinburgh, who was in the habit of initiating his students by making them practise "veterinary surgery"—the forming of a diagnosis independent of the questionable advantage of the patient's own account of his condition. It is unfortunate that the great mass of veterinary observation lies beyond the reach of even the medical man who takes the broad view of his subject. Many of the papers read at the above Conference had a direct medical interest—for example, Prof. S. H. Gaiger's discussion of the anaerobic infections in domestic animals. One can scarcely doubt but that an investigation of these conditions, as they occur among animals, will throw light on the anaerobic infections to which man is subject. A paper by Dr. J. B. Orr on the effect of nutrition on the incidence of disease was characteristic of the present trend of medical thought which was so long under the influence of purely bacteriological conceptions. In this connexion the veterinary practitioner has much to contribute. It is doubtful whether in the past more attention has not been paid to the feeding of stock than to the nutrition of the human race. Animals kept under what are at best artificial conditions demand in no small degree the applications of principles of feeding and hygiene which are based on sound scientific investigations or are the outcome of an interested empiricism. But between this accumulation of clinical knowledge, whether traditional or the result of research, and its application to human nutrition and the prevention of disease there has been in the past a great gulf fixed. That this gulf is now being bridged is largely due to the realisation—in America rather than in this country—that in the investigation of the physiology and pathology of domestic animals a double end is being served, the first an economic one, the second an illuminating of many dark places in the science of human medicine.

RECOVERY FROM SPINAL FRACTURE.

IT is a curious fact that hitherto little information has been available as to the ultimate fate, as a class, of persons whose spines have been fractured. Dr. Augustus Thorndike, of the Surgical Division of the Maria Hospital in Stockholm, has recently[1] attempted to fill this gap in our knowledge by seeking an answer to the question: What is the fate of these patients in terms of ability to work? At his hospital between the years 1914 and 1924 there were 47 cases of fracture of the spine; they were consecutive, unselected cases, in all of which the diagnosis was confirmed by X ray examination, an operation, or a necropsy. Only in six cases were the fractures confined to the spinous processes. The bodies of the vertebræ were involved in the remaining 41 cases, 34 of which were unassociated with signs referable to the spinal cord. The fractures were cervical in 8 cases, dorsal in 18, lumbar in 18, and sacral and coccygeal in 3. The most frequent site of fracture was from the ninth dorsal to the fourth lumbar vertebra, and in as many as 16 cases two or more vertebræ were injured. The accidents were industrial in 57·7 per cent., and as great a proportion as 81 per cent. of these industrial

Insurance Act. After a protracted hearing the case resulted in a verdict for the medical man, with £100 damages. Such a case as this will help to improve the position of medical men practising among miners. Reference is again made to the extreme importance of securing an X ray photograph in a case of suspected fracture or dislocation. This we referred to in a similar connexion some months ago,[1] and is emphasised in a clinical note which appears on p. 649. During the year the solicitors were consulted on several occasions by medical men holding public offices where the attempt was made by the public authorities under whom they were employed to reduce their salary, and it was pointed out that where a contract provides for the employment of an official at a fixed salary, that salary cannot be reduced save by mutual consent, and the only way of enforcing reduction is by termination of the existing contract and the creation of a fresh contract at a reduced salary. This view, the solicitors state, has now been adopted by the Ministry of Health. A word of advice on the conduct of any case is always valuable, and the solicitors make a special appeal to medical men consulting them that a full statement of the facts bearing on the case directly or indirectly should be made, and they add: "Members of the medical profession will appreciate that the correct diagnosis and treatment of a case may depend on details or symptoms which appear to the layman to be insignificant and to have no bearing. This is equally true of legal matters." An interesting case is reported where a complaint was made against a medical man of employing a woman to attend childbirth who was not certified under the Midwives Act of 1892. The solicitors warn medical men to be on their guard against the presence of unqualified midwives at any obstetrical case. Such women are liable to make use of doctors to cover them in their practices. Medical men by virtue of their calling are practically under obligation to attend any case of emergency, but when they are called in by an uncertified midwife they run a considerable risk if they sign a certificate to enable the mother to obtain maternity benefits under the National Health Insurance Acts. It is wise for physicians, if they receive a series of these emergency calls from uncertified women, to make it strictly clear either that they will not respond to any future calls or if they do respond that the woman in question must at once leave the case.

As an instance of a liability which may be unwittingly incurred in connexion with the sale of a practice by a medical man, the following case is worthy of quotation in some detail. The solicitors state:

> A member of the Union inserted an advertisement in the medical press notifying his intention to dispose of his practice and inviting purchasers to communicate direct with him. He advisedly did not consult agents, as he preferred to effect a sale without their intervention. That this practice was for sale came to the knowledge of a certain firm of medical transfer agents, who wrote the member informing him that they were sending down certain possible purchasers. The member did not acknowledge this letter in any way, though he saw the gentlemen who were sent by this firm, but he did not come to terms with them. Subsequently, another would-be purchaser came down, who was sent by these agents, which fact was never communicated to the member. Eventually, this gentleman purchased and the agents put forward a claim that the sale had been effected through their instrumentality. We were thereupon consulted by the member. The fact that the member had seen the original would-be purchasers sent down by these agents without informing them that he refused to deal with them in any way, in our opinion, was tantamount to accepting their services, and we thought that in the circumstances the Court would recognise their claim. We are glad to say, however, that we were able to induce the agents to accept a reduced fee.

If medical men avail themselves of the assistance of medical transfer agents, even though such assistance is volunteered and not invited, they may make themselves liable for the services thus rendered, and it is therefore advisable to refuse this assistance at once if it is not desired.

The benefits of the Union have been increased in two important directions. The first is geographical, in that membership is now extended to medical practitioners practising in the Irish Free State, Northern Ireland, the Channel Islands, and the Isle of Man; the second is financial, as from May 1st, 1924, the indemnity against damages and costs of the other side is unlimited. This latter extension is the outcome of the alarm caused in the profession by the damages originally imposed by the High Court in the Harnett case, and the policy of unlimited indemnity has been adopted both by the Medical Defence Union and the London and Counties Medical Protection Society. The solicitors' report ends with a tribute to the esprit de corps among members of the sister profession of medicine, which it would, perhaps, hardly be seemly to quote in these columns.

EDUCATIONAL FACILITIES FOR MENTALLY DEFECTIVE CHILDREN.

THE problem of the mentally defective child is one with which sociologists have of late been much concerned, as the discovery that such children may be the pupal stage of certain social parasites—the unemployables—is of recent date. Yet there is evidence to show that thoughtful and adequate educative measures adopted towards these unfortunate children can make them in many cases worthy members, however humble, of the community. The Board of Education have for some time had under consideration the position of mentally defective children in the country generally, and they have recently issued a Circular (No. 1341) to the local education authorities, inviting coöperation in doing all that is possible under existing circumstances to ameliorate the lot of such children. At the moment it is impossible to make fully adequate provision for this work, owing to defects in obtaining suitable accommodation and funds, but, the Board points out, much can be done, even under present conditions, towards realising the aims of the Mental Deficiency Act of 1913 and the Elementary Education (Defective and Epileptic Children) Act of 1914. The first duty devolving on the local education authority is to make a thorough ascertainment of all mentally deficient children in their area who will therby fall into two classes: first, those who ought to be notified forthwith to the Mental Deficiency Committee, and second, those who ought to be sent to special schools. Legal responsibility for the first class ceases as far as the local authority is concerned on notification. The second class, the important one, is further subdivided at present of necessity into two groups—namely, those for whom special school accommodation is available, and those who, in the absence of such provision, must either attend the public elementary schools or stay at home. Children in the special schools are supervised, under the Act, up to the age of 16, when they are either discharged as fit members of society, or, if need be, notified to the Mental Deficiency Committee and placed in institutions or under guardianship. Where no special school exists supervisory arrangements can be exercised through school nurses, care committees, paid welfare workers, or voluntary organisations, towards the cost of which the Board are prepared to furnish reasonable grants. At the age of 16 the mentally deficient child passes out of the sphere of the local authority, and it is at this point that a most serious gap exists in the educative machinery, as notification of appropriate cases to the Mental Deficiency Committee is often overlooked. The Board emphasises most earnestly the duty of the local authority in passing under review periodically all mentally defective children under the age of 16 in order that this gap may be bridged, and that the children may not be lost in the general population only to be rediscovered by the Mental Deficiency Committee or the police when from lack of supervision and help they have got into trouble and may have done serious damage both to when out of health. The benefit popularly derived from a change of air may, indeed, possibly be due rather to a change of water. The human body is sensitive to the influence of physical agencies, the effects of which are apt to be overlooked by reason of their very simplicity and familiarity. There is the added difficulty of clearing the stage for a single remedy of any kind, and it is especially difficult to separate what is essential in climatic treatment from what is accidental and adventitious. So much, however, has been learnt of the intimate physical characters of water and waters in the last 20 years that the claims of hydrotherapy may well have to be considered in the light of them. Dr. Fox's book is of value in providing theorems which can be put to an exact test. He crystallises his conclusions into 50 aphorisms, such as the following:—

---

[1] THE LANCET, 1924, i., 1115

(9) As there is an optimum temperature for life, so disease may be regarded as a question of heat.

(17) Deep-seated organs are affected by operating on related areas of the skin.

(22) The vapour bath counteracts the ill-effects of the British climate.

(36) Many remedies cure by intensifying a chronic process.

(44) Cardio-vascular invalids are best treated in their own country.

These challenges to medical thought may be taken up with some gusto by those who think otherwise and lead to a rediscussion of some too readily accepted views. The brief section in Dr. Fox's book on the choice of a spa hardly does more than touch the fringe of large and debatable questions.

THE PRINCIPLES OF TONSILLECTOMY.

THE tonsil shares with the appendix the unenviable reputation of causing more trouble than it is worth in the economy of the body, for there is no evidence to show that tonsillectomy even in infancy destroys an important function from the lack of which a patient would suffer, while it is generally believed that enucleation lessens the liability to infectious diseases. Dr. A. Brown Kelly, in a discussion of the subject at the recent annual meeting of the British Medical Association, at Bradford (Section of Laryngology and Otology), said that the two most common pathological conditions of the tonsils were sepsis and hypertrophy. The latter condition, he held, was most common in children, and there need be no hesitation in removing the tonsils and adenoids from a healthy child of 2 years or even 18 months. Tonsillar sepsis rather than hypertrophy was associated with adults, and, indeed, many tonsils which on inspection and on squeezing were apparently healthy, were on microscopical examination found to be diseased. The faucial tonsil is particularly adapted for the production of septic foci. The detection of a septic focus in a tonsil, Dr. Brown Kelly said, was a matter of great importance and sometimes of some difficulty, but the presence of caseous plugs in the crypts and enlarged cervical tonsillar glands was a valuable aid to diagnosis, although the absence of these signs did not preclude the presence of a small encapsuled abscess in the tonsil. He mentioned several points which had to be noted in advising operation in cases which suffered from systemic diseases known to be caused at times by septic tonsils: (1) if the focus was found, or if the patient was liable to attacks of tonsillitis and cervical adenitis, the tonsil should be removed and the patient told that the local condition would be cured, but that the improvement of the systemic disease could not be guaranteed; (2) if the onset of the tonsillar infection coincides with that of the systemic disease, the focus was probably in the tonsil; (3) if there were other septic foci—in the teeth, sinuses, or alimentary canal, these should be eliminated before advising tonsillectomy; (4) if the tonsil was clinically healthy, and there was no evidence pointing to a relationship between the tonsil and the systemic disease, enucleation of the tonsil should not be recommended. At the conclusion of the meeting resolutions were unanimously passed (1) that tonsillectomy by enucleation was the only effective operation; (2) that the operation should not be conducted as a minor operation, but as one of the lesser major class of operation; and (3) that the operation should only be undertaken after expert opinion had been given.

THE first social evening of the session at the Royal Society of Medicine, 1, Wimpole-street, W., will be held on Thursday, Oct. 16th, at 8.30 P.M., when Fellows and guests will be received by the new President, Sir StClair Thomson. At 9.30 P.M. Dr. W. T. Grenfell of Labrador will give a brief discourse, with lantern illustrations, on "Medicine in a Corner of the Empire."

Sir Robert Blair, who recently retired from the post of education officer to the London County Council, is one of the candidates for the chairmanship of Convocation of London University. His election would bring to Convocation a wealth of educational knowledge and experience such as few possess, and the support he gave to the medical staff in the service of the London schools is sufficient guarantee that he would serve well the interests of medical education.

The Services.

COLONIAL MEDICAL SERVICE.

THE following appointments have been made in the West African Medical Staff: Dr. T. A. Dowse to be a senior sanitary officer in Nigeria, in succession to Dr. W. S. Clark, promoted, and Dr. P. S. Selwyn Clarke to be a senior sanitary officer in the Gold Coast, in succession to Dr. A. C. Lorena, who is about to retire from the service.

ROYAL ARMY MEDICAL CORPS.

Maj. K. A. C. Doig retires on retd. pay on account of ill-health.

Capt. (prov. Maj.) H. W. L. Allott reverts to the substantive rank of Capt.

ROYAL AIR FORCE.

Flying Officer E. D. Gray is transferred to the Reserve, Class D.2.

INDIAN MEDICAL SERVICE.

Majs. A. F. Hamilton, A. A. McNeight, A. D. White, H. C. Buckley, N. M. Wilson, J. S. O'Neill, M. R. C. MacWatters, W. H. Hamilton, and J. Cunningham to be Lt.-Cols.

Capts. S. Gordon, B. F. Eminson, A. Kennedy, and J. C. John to be Majs.

The King has approved the retirement of Lt.-Col. N. W. Mackworth.

Lt. Nilratan Chatterjee relinquishes his tempy. commn. and is permitted to retain the rank of Lt.

DEATHS IN THE SERVICES.

Surg.-General William Richard Browne, C.I.E., I.M.S., retd., who died at Soldanelle, Rougemont, Switzerland, on Sept. 16th, at the age of 74, joined the service, in which he had a distinguished career, in 1873. After holding various positions in Southern India, and seeing service in the suppression of the Rumpa Rebellion 1879–80, he became, in 1883, resident surgeon in the Madras General Hospital and professor of pathology in the Medical College, a position which he held till 1890. In that year he was appointed professor of surgery, and later was elected a Fellow of the College. In 1901 he became the Principal of the Medical College. Subsequently Surg.-General Browne returned to army duty, and was appointed P.M.O. of the Madras district. In 1905 he was appointed surgeon to the Viceroy and retired in 1908.

THE WEST AFRICAN MEDICAL STAFF LIST.

WE have received from the Colonial Office a copy of the West African Medical Staff List (Waterlow and Sons, Ltd., London) containing the appointments to the staff as on July 8th, 1924. The list of medical officers is given first in seniority, then by colonies, and finally an alphabetical list with their services. Officers who desire additions or corrections to be made in their records of service should communicate with the Editor of the W.A.M.S. List, Colonial Office, Downing-street, London, S.W. 1.

accidents concerned the building trade, dock and common labour. After discussing briefly the modern treatment of fractures of the spine, Dr. Thorndike gives an account of the issue in his series. Of the seven patients whose spinal cords were injured, five died, one remained in hospital, and one could not be traced. Of the 40 patients without spinal cord symptoms, three were still in hospital, three had died of causes other than the accident, and ten could not be traced. Of the 23 patients who were re-examined by the X rays, all were found to have recovered sufficiently to return to work—in most cases to full-time work at their former occupation. The most important feature of this paper is its lesson that, given time and proper treatment, most fractures of the spine, provided the cord is not compressed, do not permanently incapacitate the patient who, if his occupation is clerical and not manual, may expect to return to his former work without loss of efficiency. The manual worker may also hope to do so, but after a longer interval than the clerical worker requires. The average time lost by those of Dr. Thorndike's patients who recovered was 330 days —a period long enough to disable financially most workers for whom there is no accident insurance. Dr. Thorndike concludes with the hope that more statistics may be published on this subject so that comparisons can be made between his material and larger series of cases.

THE SKIN CIRCULATION.

The demonstration, within recent years, of the independent contractility of the capillaries, together with improvements in technique for the examination of the skin capillaries, has caused a good deal of attention to be focused on the circulation in the skin. We know, for instance, that the colour of the skin gives an indication, and a very valuable one, of the condition of the capillary vessels within it, while the temperature of the skin surface enables us to judge of the state of the skin arterioles. Thus the skin can be cold and blue, indicating dilated capillaries and constricted arterioles, or cold and white, showing general vascular constriction, or warm and red when all the vessels are dilated. The study of cyanosis thus takes on a local as well as a general aspect. An account of this interesting subject may be studied in Prof. August Krogh's work on "The Anatomy and Physiology of Capillaries" (1922, Yale University Press). Some of the reactions of the skin to stimuli are also of considerable interest. After the application of mechanical stimuli to the skin there is often a transient red flush followed by the appearance of a localised constriction indicated by intense pallor. Sir Thomas Lewis has shown that this is a constriction of considerable intensity requiring a good deal of internal pressure to open up the capillaries again. The contractility of the skin vessels is to a considerable extent independent of the central nervous system, and, according to Prof. J. van Breemen,[1] thermal excitation provokes vascular reaction even after section of the cutaneous nerves. In an important article he shows how there is a definite relation between the amount of blood in the skin and that in the deeper structures of the body—the so-called law of Dastre and Morat—expressing this by saying that these amounts vary in inverse ratio. There is also believed to be a relation between the blood in certain parts of the skin and that in certain definite internal parts. Thus stimulus applied to the foot causes a contraction of the blood-vessels of the kidneys, while the stimulus of cold applied to the inner side of the thigh causes contraction of the uterine vessels. Further, there is a relation, expressed by the term "consensual reflex," between the skin of the two sides of the body. In accordance with this law, the application of cold to the skin of one arm will cause constriction of the skin vessels of both arms, as may be proved by plethysmographic tracings. Another characteristic of the skin circulation, to which Prof. van Breemen draws attention, is the extent to which it is affected by the contraction of the skin muscles. When the arrectores contract, not only does an erection of the hairs follow but the skin is emptied of blood as a result of the pressure put upon it. These facts are of practical interest in connexion with the mechanism of "taking cold," about which Dr. S. E. Kark writes on p. 683, and it would be interesting to know more about them.

THE NEW MEDICAL BUILDINGS AT CLEVELAND.

A member of our staff who has returned from a visit to the newly completed block of medical buildings at the Western Reserve University, Cleveland, Ohio, found that they left nothing to be desired as regards structure and equipment. The ground-plan of the block, situated in the suburbs of this beautiful forest city, is in the form of the letter E; the middle wing is occupied by staircase, and the L-shaped portions on either side of this contain the various departments. There is a large separate power-house and a central plant, from which refrigeration is "piped on" to each floor to supply rooms at suitable temperatures. Each department has its own well-equipped library and lecture room, and there are abundant research rooms, in which work has already commenced. The laboratories are equipped with every modern need in the way of benches, fume cupboards, compressed air, vacuum, distilled water supply, and so on, but there has been no money wasted on extravagant halls and staircases. Features of especial interest are the departments of pharmacology, experimental medicine, physiology, and anatomy. The teaching part of the pharmacology department, under Prof. T. H. Sollmann, comprises an excellent laboratory for chemical pharmacology, as well as the usual experimental pharmacology department; the department of experimental medicine, under Prof. Neil Stewart, is actively occupied with research work, especially on the suprarenals; the physiological department, directed by Prof. C. J. Wiggers, has admirable student arrangements for the study of human and mammalian physiology, as well as fully-equipped laboratories for the special investigation of the circulation. The most striking department, to an English visitor, is the anatomical, under the direction of a Manchester graduate, Prof. T. Wingate Todd. This is fully equipped for teaching and research, has a remarkable museum, and a surprising collection of human and animal skeletons, all fully described. The system of collecting data relating to the cadavers is noteworthy, as are also the arrangements for making skeletons, of which some 1200 have so far been collected in the course of a series of investigations on quantitative human osteology. We offer our sincere congratulation to the Western Reserve University and to Prof. Sollmann, who, as chairman of the Constructions Committee, has had much of the arrangements in hand, on a remarkable achievement for the advancement of medical knowledge.

MIXED DRINKS.

There is a tendency, Dr. R. Fortescue Fox remarks,[1] for water-supplies to become more and more a compound of many sources, so that the great majority of people are compelled to drink mixed waters and never drink from a single source. This is true of the natural waters of lakes and rivers as well as of the water laid on in London and other large centres. Only the spring is an unmixed product, and from this basis Dr. Fox goes on to develop the theme, started in a series of lectures given at the University of London, that there may be some distinctive quality of value in water from a single spring. In many parts of the world, he mentions especially India and the West of England, there is a strongly-rooted popular belief in the efficacy of a change of water the mental attitude of the individual, a discussion in which the physician may at times advantageously adopt the Socratic method after the patient has laid down his own point of view.

Revival of a Lost Memory.

It is a matter of judgment how much the patient should be pressed with direct questions, but where time permits it is better to wait patiently rather than, by producing denials, make subsequent avowals difficult. An ever-recurring trouble is remorse at masturbation, past or present, and the physician must be courageous enough to recognise that the dreadful effects ascribed to it are imaginary, that the habit is so common as to be almost a typical phase in sex development, and that the greatest problem in regard to masturbation is the horror we profess towards it. If the physician is able to adopt this attitude he finds less difficulty in dealing with the associated remorse; but even then he may fail, and a slight acquaintance with psycho-therapy enables him to recognise that he is dealing with an emotion arising from some deeper complex and secondarily attached to the masturbation. This displacement of emotion is characteristic of nervous symptoms and is of practical importance in treatment. A simple technique consists in placing the patient upon a couch, making him describe and, if possible, feel the emotion concerned—the feeling associated with a specific phobia, for example—and urging him to remember any occasion in the past on which the same emotion was felt. This method was successful in the war cases, and if the practitioner only once revives a lost memory by it he gains an insight into mental processes which reading does not give him. While a full analysis may not be practicable for the practitioner, he should be able to recognise those cases in which the severity of the symptoms demands it and the age, temperament, and circumstances of the patient render it possible.

The physician's influence must be used in supporting the patient and encouraging him to carry on the duties of life. Since a minor psychosis is, from one aspect, an attempt to escape from difficulties, the patient should be encouraged to persevere in spite of his symptoms. A practical point is that if a man wakes up fit in the morning, but soon tires and becomes "washed out" before the day is over, he needs a holiday; but if he wakes depressed and unrefreshed, to improve as the day goes on and become fit by the evening, he needs treatment for his anxiety and stimulation to stick to his work. The aims of the family practitioner should be to clear up those causes of anxiety which are accessible and to gain a personal influence by properly understanding the patient. The successful treatment of anxiety states must, like all treatment, depend upon experience. There is no lack of material. The real difficulty facing the practitioner is to find time *properly* to investigate it.

Lecturer on Psycho-Neuroses, London Hospital
Medical College.

DUST AND DISEASE FROM THE CARDING OF WOOL.
A clause in the new Factory Bill *requires that* "where there is any dust or fume of an injurious or offensive character, or any substantial quantity of dust of any kind, all practical measures shall be taken to *protect the* workers against inhalation of the dust or fume." It is also stated that where the nature of the process permits or makes it "practicable" exhaust appliances shall be provided and maintained as near as possible to the place of origin of the dust or fume. The operatives contend that the large amount of lung disease and suffering from lung complaints is due to the excessive amount of dust in the cardroom. With a view to arrive at a satisfactory solution *and agreement*, Mr. E. F. May, superintendent-inspector of factories and workshops for the East Lancashire division, and representatives of the employers and operatives jointly have *visited some selected mills* in Oldham and Rochdale. Other mills will be inspected, and it is hoped that this joint committee will reach a satisfactory arrangement before this particular clause of the new Factory Bill is laid before the House of Commons.

Special Articles.

PUBLIC EDUCATION IN HEALTH.

SIR GEORGE NEWMAN'S MEMORANDUM.

Sir George Newman has submitted to the Minister of Health a Memorandum on the subject of Public Education in Health (H.M. Stationery Office. 6*d*.), prepared some months ago, but delayed by pressure of official work. In this Memorandum the Chief Medical Officer reviews the remarkable voluntary health movement which has characterised this country for many years past, and in which Great Britain has taken the lead among the nations; but that other means and methods are now available, some of them more formal and official than in earlier days does not, he says, detract from the honourable and valuable work accomplished by the pioneers. The time seems now to have come when the responsibility of central and local authorities in this matter of public education in health should be more fully appreciated, particularly in view of the fact that national health organisation has not kept pace with advance in the science and art of preventive medicine.

The Memorandum deals successively with the personal aspect of preventive medicine, the educational work of the Ministry of Health, of the Board of Education, of local authorities, of voluntary bodies, and public health education in other countries. At the end Sir George Newman makes some general observations on the present position in England and Wales, and draws some conclusions which are thus tersely set out. First, there has been a growth of knowledge in the science and art of medicine and its application to many morbid conditions now known to be preventable; secondly, there has been a rapid development of the whole system of sanitary governance and public medical services—*and public opinion has not kept pace with these two profound changes.* Yet without an enlightened public opinion the measure and value of scientific and legislative advance is impaired. It is true that attempts have been made—all of them public-spirited, many of them gallant, and a few of them even heroic—by the voluntary service of persons or societies to meet this situation and fill the breach. On the whole these efforts have met with encouraging, and sometimes enduring, success. But such enterprise is in need of guidance and support, and is liable to some degree of misdirection. It lacks unity, tends to become chaotic, is without adequate supervision, and is, all too often, insufficiently related to the new knowledge and the expanding organisation.

More Effectual Organisation.

The Memorandum suggests the need for full inquiry into the educational functions of local authorities and voluntary societies with a view to their more effectual organisation.

(*a*) All local authorities are indirectly engaged in educational work inseparable from the effective discharge of their *statutory duties under the Public Health Acts*, and this aspect of their services is paramount. It is on the whole the most important and universal form of public education *in health*.

(*b*) Some local authorities, in addition, are undertaking supplementary educational work of a more direct nature, though *others* are, or deem themselves to be, debarred or at least restricted in this more direct sphere of education. It seems to me desirable that any ambiguity on this point, or *in* the law *itself*, should be removed as soon as possible, so that upon all local authorities there should be *imposed* a power or a duty of direct educational work.

(*c*) Then I think the time will have come for the Government to consider whether such educational work is of sufficient importance and value to be assisted financially by an Exchequer grant under the Ministry of Health, which would naturally take the form of a provision available to local authorities for certain approved types of educational work in hygiene.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

LXXXIX.

THE TREATMENT OF ANXIETY STATES.

PATHOLOGICAL anxiety occurs in many conditions, but the patients here to be considered are those where anxiety is shown as the chief characteristic—often associated with obsessional symptoms or hysteria—though this cardinal symptom is frequently masked by physical symptoms. Headache, insomnia, fainting spells, heart trouble, dysmenorrhœa, asthma, dyspepsia, mucous colitis, and the like, are found in anxiety states; the influence of emotion upon bodily functions accounts for the association, and when attention is directed to the mental state these physical manifestations can often be notably influenced.

The Avoidance of Physical Treatment.

Physical treatment need not be considered in this article, since it is obvious that the general health of the patient must be attended to and any gross lesions treated; but it should be made clear at the outset that the doctor does not regard any physical trouble as the primary cause of the mischief. Recovery depends largely upon the patient's own handling of the situation, and any emphasis upon physical troubles, though acceptable to the patient as a means of escape from facing the situation, is for that very reason to be avoided. The search for something that can be treated by physical means, with neglect of the mental state, leads to chronic invalidism. We have to avoid the extremes of regarding the patient as suffering from a physical disorder or, on the other hand, of telling him there is nothing wrong with him. He may often be led to accept the proposition that physical disease is absent if we follow it by the remark that though his physical health is good, yet there is obviously *something* the matter or he would not come for treatment.

The sympathetic elucidation of mental symptoms is the first step in treatment, and it will be found that whilst the nervous patient talks interminably about his aches and pains, he is reticent and elusive concerning his fears and inhibitions, and more obstinate still in concealing such causes for his trouble as he may be aware of. One cause for the reticence is that in the past doctors did not seek for these symptoms, and perhaps even, by dismissing them as trivial or imaginary, discouraged the patient from revealing them. Only when he realises that the mental symptoms are regarded as being in need of treatment will he talk about them; it is now recognised that there is no danger of producing mental symptoms by "suggestion," though many nervous patients readily accept and cling to a diagnosis of physical disease.

If we waited for patients to complain spontaneously about a fear of being in closed rooms we should regard claustrophobia as a text-book curiosity, and the ready acceptance of faintness in a close atmosphere as a physically induced phenomenon easily prevents understanding. General complaints of loss of memory, inability to concentrate, of depression or nervousness, are met by a request for examples. "What sort of thing makes you nervous?" will often bring out unsuspected fears and inhibitions, though it may be necessary to ask specifically about such trouble as fear of tube trains, of being in the dark, or of sitting alone in a restaurant. The feeling of being observed may be either little more serious than the shyness of adolescence, or a most distressing symptom, no less distressing because its irrational nature is fully realised by the patient. Obsessional symptoms, of which one of the commonest is the need to return several times to make sure that a door is fastened or that the gas is turned out, are themselves productive of anxiety and indicate a condition more deep-seated than the more simply handled pure anxiety state. Anxiety and obsessional symptoms are but meagrely described in our text-books, but those who realise that pathological anxiety arises from causes unknown to the patient and may remain floating loose—a fear of nothing in particular—or may attach itself irrationally to any conceivable object, soon learn from patients its manifold manifestations. Nervous breakdowns are often exacerbations of an anxiety state, and most of the cases of "neurasthenia"—even "traumatic neurasthenia"—are examples of pathological anxiety.

The Physician's Difficulties.

The minor psychoses (and under this title are grouped hysteria and anxiety and obsessional states) are generally a reaction to current difficulties; the type of psychosis is determined by the temperament of the individual and by previous troubles, and the causes—even the current ones—are not recognised as such by the patient. The commonly ascribed causes, such as overwork and stress and worry of various kinds, can only pull the trigger—they do not load the gun. The aim of treatment is to make the patient aware of his difficulties, and according to circumstances (of which the temperament of the physician is an important one) the methods range from explanation and kindly insistence up to the full technique of psycho-analysis. In any case the more the patient is encouraged to talk out his own troubles the easier will it be for him to understand himself. The mere discussion of symptoms hitherto hidden from everybody will give some relief and help to establish that *rapport* necessary for therapy. Only when this *rapport* is established can the patient be expected to bring forth such emotional difficulties as may be present. Here the temperament of the physician becomes of importance, and it must be admitted that our own resistances play a great part in hindering the patient. For example, we have in the course of our training overcome a more or less artificial resistance against accepting as a matter of fact the discussion of the anatomical details of sex, but the mental aspect of it is still subject to the social taboo. The sensitive patient will note the slightest sign of antipathy on the part of the physician and will keep back what may be essential to the understanding of his case and himself. It is a good working rule to assume that in every anxiety case there is something kept out of consciousness and that it is kept out because it is repugnant to the patient. This suppressed material is heterogeneous, but is most commonly, for obvious reasons, connected with sex. It must be accepted as an empirical observation that the bringing of the material into full consciousness, and the necessary overcoming of resistance in the process, brings relief to the patient and lessens the amount of pathological anxiety. Hence, it is plain that the physician who possesses resistances identical with those of his patient can be of little help to him and will fail to understand what he is dealing with. If he has overcome his own resistances he soon finds that in adults a minor psychosis rarely exists when the sex life is running smoothly. He hears stories of frigid wives and impotent husbands, and discovers that when one spouse comes for treatment it is often the other partner who needs it; that unhappy marriages can induce a minor psychosis, and conversely that a minor psychosis leads to unhappiness in marriage. He recognises the perniciousness of the recommendation—still frequently given—of marriage as a cure for "nerves," for anxiety often arises from fear of sex or of sex desire, and marriage in such cases leads to disaster. He may find that the patient is faced with an insoluble problem. But even then the realisation that the anxiety has served as an escape from facing the problem may help the patient. In many cases, fortunately, relief is to be found in a discussion of which they contracted the disease, after just enough treatment at a sanatorium or hospital to enable the patient to leave the institution. The patient relapses in most cases and infects his fellow workers.

Mode of Inquiry.

Information was obtained from various sources: (*a*) By questionnaires circulated to the medical superintendents of recognised sanatoriums (with attached training sections), to tuberculosis training and treatment colonies and settlements, to the branches of the Society of Medical Officers of Health, and to tuberculosis officers; (*b*) from publications of British, American, and continental authorities and committees; (*c*) from personal experience of patients at the Devon and Cornwall Training and Employment Centre and Settlement, at Papworth and Preston Colonies, at the Treloar Hospital, Alton, the Shropshire Orthopædic Hospital, the Maltings Farm Sanatorium, and elsewhere.

The replies received were without exception in favour of employment at a sanatorium with training section, afterwards at a colony or training centre, followed by agricultural or industrial occupation under medical supervision and hygienic environment—always in suitable and selected cases. In the majority of cases patients were found to improve in physical, mental, and general condition. They put on flesh, there was less cough and spit, but especially occupation helped to remove discontent, and with the prospect of becoming wage-earners patients became brighter, more reliable, and less querulous.

The replies as to the effect of employment under ordinary industrial conditions, the patients living at home, showed very variable results. There was the usual tendency to resume the old occupation, as the fullest remuneration could be earned at it. If the conditions of this were not satisfactory and if patients could not regulate their life according to their state of health, relapses were common. On the other hand, if the conditions of work were satisfactory or fairly so, and the factors producing the disease (such as bad home surroundings) were improved, the general health might be maintained. As long as the health continued fairly good, the ability to support themselves and their families resulted in a contented mind and removed the worry, which had such a depressing effect on a willing individual. Mental health and outlook usually improved with employment, although physical relapse frequently occurred, especially if the housing was bad.

Care and After-Care.

The replies showed that care and after-care were necessary and should be continuous; that when thoroughly carried out such care was of therapeutic value and of economic assistance to the patient and to the community; that care should be organised both (*a*) as to the character and methods of training and employment, (*b*) as to the financial assistance in such schemes, and (*c*) in the maintenance of the patient and his family by the State and the local authority with real voluntary helpers. The State should approve, define, and forward the scheme, the duty being laid upon the local authority to work it out by a combination of agencies.

The housing of patients while training should be in colonies or village settlements—i.e., after sanatorium treatment and training, and also when permanently employed, if their physical condition indicated the continued need for such a life. For those who returned to their homes and were employed under supervision in work-rooms or allotments, or under ordinary industrial conditions in the vicinity of their homes, suitable housing should be provided, controlled, supervised, or improved, if necessary, by the local authority.

My personal experience is that there are numbers of patients whose future existence depends on suitable employment under medical supervision in healthy conditions, *after* adequate treatment (with or without training) at a sanatorium, and on continuous care and after-care. No training centre, colony, or workshop should be approved or established except under medical supervision and control. Such centres should be regarded as commercial sanatoriums for sick men, not as business propositions; if run as such they will be dismal failures. Unsuitable or unregulated work undertaken, when treatment by rest or graduated exercise in a sanatorium is indicated, is a danger. There are definite medical contra-indications to work. Suitable temperament is essential to success as a trainee or colonist, and the "work-shy" civilian or ex-Service tuberculous patient is useless for employment. With a number of ex-Service pensioners for tuberculosis the award of 100 per cent. pension (whether the disease is active or not) results in disinclination towards useful work of any kind. For years these men have done no work, partly because there has been no need or call to do so; some are young, others middle-aged. The civilian has the habit and need to work, in him the *inclination* exists, and he makes a suitable trainee or colonist.

I have no doubt that the State and local authority, assisted by local voluntary agencies, should organise and finance complete schemes of care and after-care. It cannot safely be left to voluntary agencies, which have not as a rule the knowledge, enterprise, or money to get things done. *They talk much and often do little.* On the other hand, the local authority may not have the vision, and acts only under compulsory, not permissive, legislation. The right spirit must animate both State and local authority. Given initiative, together with the resources of the State, success will be sure.

Conclusions.

1. Adequate treatment for both pulmonary and non-pulmonary tuberculosis in sanatorium or hospital must precede employment in all cases—viz., convalescent after active disease, quiescent or chronic and incurable.
2. Employment is good, both physically and mentally, if the patient is fit for work and the work is prescribed in regulated "doses" under medical supervision.
3. The constant medical supervision of a complete care and after-care organisation prevents the spread of tuberculosis and lessens the sickness-rate of the disease.
4. A complete care and after-care scheme, affording training and remunerative employment, is of economic value both to the patient and the community, and lessens the financial burden to the nation.
5. Provision should be made by the State and by the local authority for training sections or "extensions" for men, women, and children at sanatoriums and hospitals, such patients to be selected on medical grounds.
6. Provision should also be made for training and treatment centres and village settlements for temporary or permanent residents under medical supervision.
7. Industrial and agricultural training and employment should be available at such centres.
8. Workshops should be provided in such centres and for urban districts under medical supervision.
9. The State and the local authority should organise such centres, assisting financially the patient and his family to exist during incapacity, partial or complete.
10. Voluntary agencies should assist in such schemes as (5) and (8).
11. *Housing.*—Patients while training in sanatoriums or residential settlements, and after training during employment, should be housed at such centres, as long as their physical state indicates the need. Those who have returned to their homes and are employed either in municipal or approved workshops or allotments, or under ordinary industrial conditions, should receive the assistance, supervision, and control of the State and local authority in housing when their home circumstances require this.

Recommendations.

I submit that there is need of inquiry and action by the Government, either by a Departmental or Inter-Departmental Committee, or by inclusion in the proposed Royal Commission on the Medical and Allied Services under the National Insurance Act. Need for organisation arises because there is an incomplete and, therefore, wasteful medical tuberculosis service, defective in its principles and in its complete medical care of patients. Inquiry by Departmental Committees in 1912, 1913, and 1919 approved occupational training in sanatoriums, training colonies, and village settlements, the last for ex-Service men only. The responsibility for establishment and maintenance for these institutions was placed on the Ministry of Health and £1,250,000 was proposed to finance these developments, which did not materialise. The demand now is for an inquiry into the extent of and solution of the problem on a national basis and including the whole civilian population.

The number of patients for whom *accommodation* is required in training centres, or in colonies or settlements, should be ascertained, with due consideration to the fact that the numbers will always be limited under a voluntary system and subject to selection on medical and other grounds. The number of *such centres, settlements,* and workshops should be estimated. The capital and maintenance cost should be arrived at. Allowance should be made for the saving in Poor-law and other forms of State relief and incapacity for remunerative industrial employment *owing to disablement* under the present lack of system.

It is futile to place responsibility for housing and after-care on tuberculosis medical officers and on after-care committees. The bogey of expense for these measures will disappear if the problem is boldly faced on the basis of facts and knowledge of their comparative cost with those of disablement and sickness.

Points for a Government Inquiry.

Put briefly, there are three points which show the necessity for a Government inquiry. (1) The tuberculosis medical service as it exists is incomplete and (*d*) Lastly, these two steps in re-defining the powers under which educational work is undertaken by a local authority, and encouraging its development, will inevitably raise the question of the extent to which, and the terms on which, voluntary societies should also officially participate in the more direct form of such instruction (as distinct from the indirect educational work inherent in an efficient sanitary service). On this subject it would not be appropriate for me here to say more than that, in my opinion, it is the local authorities who must be directly responsible for undertaking educational health work, direct as well as indirect, suitable to their own district, circumstances and needs, with such supplementary special assistance as the voluntary societies concerned may find themselves able to afford.

Supplementary Teaching.

Among the principal direct methods for providing supplementary teaching the Memorandum suggests the following: (1) The publication of annual reports, bulletins, pamphlets, leaflets, circulars, posters, &c.; (2) the preparation of special articles for the newspaper press; (3) lectures and addresses, educational classes and conferences; (4) the construction and display of exhibitions and demonstrations; (5) the use of the cinema; (6) broadcasting. In a footnote Sir George Newman adds the following interesting hints and suggestions as to details of procedure. That the method is capable of considerable development is obvious from the extent to which it is profitably utilised in similar publications for the purposes of commercial publicity. Those responsible for drafting and publishing such documents might with advantage draw on the knowledge and experience of commercial advertisers, and have regard to the technique of printing, letterpress, and display.

Annual reports should be clear and simple, and supply reliable statistics as to the work done and the needs and direction of future expansion. The weekly, monthly or quarterly health bulletin or journal has been widely used in America and Canada. It should be interesting and informing, and designed to keep teachers and instructors in touch with local public health questions.

Pamphlets and leaflets are used for purely instructional purposes in special subjects, being given to those who definitely seek the information at clinics or elsewhere. For this purpose they are undoubtedly of great value, although their application is of necessity limited to those in whom the health conscience has already been aroused.

Posters should be brief, graphic, and arresting as well as accurate.

The *Newspaper Press* inserts health articles to a certain extent in this country, but much more in America. Press matter consists of (*a*) "Copy" and (*b*) Advertisements. Copy is presented in several sub-divisions each of which can, to some extent, be used for purposes of health propaganda. *Editorial comment* is written to the order of the editor and deals only with subjects of paramount or current interest. It is only very occasionally, therefore, that it would be available in any organised scheme of propaganda. The "*news*" *story* is an expression used to denote copy which informs the reader in narrative form of any recent occurrence. Matter of this description may sometimes be made to point a sanitary lesson or introduce an item of health teaching, and "interviews" may thus be a vehicle for health propaganda. The "*feature*" *story* is a periodical article on various subjects such as music, fashion, art, &c., and many of them include information on health. It is the form not infrequently adopted for health teaching in newspapers in this country, and most editors are willing to accept it if attractively written and not too technical. The correspondence columns of newspapers, sometimes with the encouragement of the editor, are often deliberately employed for arousing interest and discussion, or even controversy, on subjects about which it is desired to make people think. Health subjects have been dealt with in this manner, and it is a device that should be borne in mind by the propagandist. Many newspaper advertisements such as those of soaps, dentifrices, toilet preparations, foods, and even patent medicines are framed in a manner calculated to arouse a desire for health that would be most valuable were they always employed for advocating sound hygiene.

Lectures, lessons, educational classes and conferences fall naturally into two groups, those forming part of the curriculum of schools or educational institutes and those delivered to audiences specially assembled for the purpose. Both groups may afford most valuable means for imparting instruction to those who desire it. The subjects should be appropriate, well presented, and amply illustrated by charts, lantern slides, or films. Originality and initiative are generally rewarded, and exhibitions and demonstrations have proved extremely successful.

The *cinema* has exceptional potentialities as a medium for public health propaganda. Practically all lasting impressions on the human mind are absorbed most readily through the visual or auditory senses, and of these two vision plays the greater part. The strength of the impression produced will depend very largely on the extent of the interest aroused at the time. In view of the remarkable development of the art of film production in the last 20 years, it is disappointing that it has not been more fully used for purposes of popular health education, but there are many difficulties, including expense, the taste of the audience, eye-strain, methods of projection, and inflammability. In American public health circles the opinion is expressed that the results of cinema methods have not come up to expectations. In order that a health film should fulfil its object it must be capable of reaching a large number by its popular appeal and of conveying its lesson correctly. The first is the business of the film producer, the second of the health specialist. These two experts have not hitherto combined effectively, with the result that in the majority of health films at present existing either the health instruction is ludicrous in its inaccuracy, besides being completely overshadowed by the dramatic effect of the film, or else the film is so packed with highly technical instruction that it fails to make a popular appeal. The cost of producing films is high, especially if only a small number of copies are prepared.

Broadcasting has shown remarkable development in the past 12 months and seems likely to continue to do so. As a means of publicity it already bids fair to equal or surpass other methods. At present its use for health propaganda, in this country at any rate, has scarcely begun, but there can be no doubt that it holds out immense possibilities in this direction. Already upwards of 800,000 listening-in sets are licensed, and as each set is capable of being used by a number of listeners simultaneously, the "circulation" of broadcasting is very large. The British Broadcasting Company has to provide for the taste of its listeners quite as much as, if not more than, the newspaper for that of its readers. Like the newspaper, therefore, it accepts matter that will please and interest its patrons and it naturally will not accept "copy" that will tempt listeners to remove their head-phones.

Sound Educational Method.

Those who would teach large masses of people the way to health must make a careful study of method. There is a problem: it must be expressed simply, clearly, graphically, and accurately; it must be steadily and moderately driven home, so that every person feels it. There is a solution: and the way out must be demonstrated in such form that the action of the individual and the community is secured. In a word, to achieve any lasting effect sound educational methods must be followed. The publicist must be a teacher, trustworthy in fact, comprehensive in conception and understanding, able to impart the knowledge which he possesses, and capable of drawing out his pupils.

A REPORT ON THE EMPLOYMENT AND AFTER-CARE OF TUBERCULOUS PERSONS.

BY F. G. BUSHNELL, M.D., B.S. LOND., D.P.H.,
TUBERCULOSIS MEDICAL OFFICER, PLYMOUTH BOROUGH COUNCIL.

THE following report was drawn up at the request of the Advisory Committee (Public Health) of the Trades Union Congress and Labour Party, the inquiry being carried out in conjunction with the West of England Branch of the Society of Medical Officers of Health. A thorough and complete system of care and after-care of tuberculous persons includes the training and employment for suitable work of selected patients who may be unable to resume their own occupation after sanatorium treatment owing to the danger of relapse; their settlement and housing; their maintenance and support of their families; their general advice and assistance; and the considerations which arise therefrom. It is felt that an end should be put to the present inhuman system of allowing persons suffering from tuberculosis to return to the conditions under

TUBERCULOSIS AND THE FEEDING OF COWS.

To the Editor of THE LANCET.

SIR,—The leading article in your issue of Sept. 20th on milk production only proves conclusively that the Milk Publicity Council is faced with a colossal piece of work, and to anyone who has interested himself in the question of milk infection with tuberculosis the position seems to be almost impossible to deal with. The whole root of the evil is that everyone is trying to treat a symptom instead of dealing with the direct cause, and until the cause is dealt with there is but very little hope that we shall ever have milk that is free from tubercle.

I have gone into the matter fairly completely and have experimented largely on the possibilities of preventing tuberculosis by hygienic methods, such as cleanliness, open air, exercise, &c., and have come to the conclusion that, good as these measures may be, they have very little influence on prevention of tuberculosis in our farm stock. I have seen tubercle amongst cattle in farm stock on farms which are run under the most hygienic conditions possible, but, nevertheless, a large number of the cows reacted to the tuberculin test. I have also visited farms where conditions have been far from perfect as regards hygiene, yet there were very few reactors. On certain farms where certified milk is being produced, I was informed that cows were constantly being discarded because they reacted and, of course, this discarding would be continuous. I found that these reacting cows were disposed of either in the local market or to another farm where certified milk was not produced. I have recently had several cows tested with a view to purchase, and not 2 per cent. but 20 per cent. failed to pass the test. There are many more tuberculous cows amongst dairy herds than one would suppose and these are not discovered until a test is carried out. We, as a profession, perhaps do not realise that one cow in a herd, say, of 100, is quite sufficient to infect the whole of the milk from the other 99 cows. The same churns, buckets, and often the same milker are used for all, and were we to slaughter all the reacting cows in Great Britain to-day the results within a few months would be just as bad. One has only to go into the question of modern day feeding of a dairy cow to realise the cause of this prevalence of tuberculosis amongst dairy cows. My experiments have been carried out chiefly on pigs, for, as we are well aware, the pig is as susceptible to bovine tubercle as is the human being. Some years ago I founded a herd of pedigree pigs and housed and bred them on the open-air system. I was constantly slaughtering animals which on post-mortem examination showed marked signs of active tuberculosis.

The percentage was often as high as 5 per cent. of animals showing pathological lesions either in the form of glandular enlargement, pulmonary tubercle or pleural effusion, or adhesions. This worried me greatly, and I considered whether it was possible to effect a cure by isolation of the dams from which those pigs had been born. I slaughtered all the mothers of any pigs that showed any signs of tuberculosis, and yet this did not cure the condition. A few years later the work on vitamins by several well-known pathologists was published, and I immediately set to work on these lines, with the result that I eliminated tuberculosis entirely from one of the largest herds of pigs, numbering well over a thousand. It is indeed a rare occurrence now to find any tubercular lesions in any of my stock. I breed some 2000 animals a year, and I have the advantage of examining some 30 carcasses a week. When one considers the natural life-history of the pig it is not indeed surprising to find tuberculosis so common amongst our farm stock. The pig normally, like the cow, will give birth to its offspring in the spring of the year, when there are trees budding, grass is growing, and where there is a good supply of vitamins in its natural foods. As the result of breeding we are now expecting our animals to give birth to their offspring at unnatural periods of the year. Furthermore, the cow was never intended by nature to supply milk for human beings, and it is indeed interesting to notice what takes place with cow and calf during the spring months. Should the calf be born about April or May, and be allowed to run with its mother in its natural state, the calf will wean itself when about 4 months old, and the cow will become "dry." She would then store up sufficient vitamin A for her general health and for her next calf. But just consider what is nowadays done. As soon as a cow has calved, may be in July or August or even in November or December, the calf is taken away from her and the cow is then milked for nine or ten months, its milk supply being stimulated by such foods as cokernut cake, palm kernel cake, cotton-seed cake, &c., none of which contain, in my opinion, any vitamin content. I carried out some experiments with these three cakes, by feeding them to pigs, giving them an adequate quantity of carbohydrate, albuminoid, oil, mineral salts, and water, yet my animals immediately began to go down hill and showed marked signs of disease, proving that none of these cakes contained the food accessories. On the other hand, when I supplied foods that were rich in the vitamins A, B, and C there was an immediate marked improvement. Just consider to-day what is the ordinary milk record over a period of 12 months of a good dairy cow; 1000 gallons is quite common, even 2000 to 3000 gallons may be produced during the lactation period, and yet this quantity is maintained chiefly by foods devoid of vitamins. Here lies the cause of the whole trouble, and I predict that unless some radical change is made in our feeding methods milk as a source of sound food for human beings, especially children, will be impossible. I have been able to trace a large amount of tuberculosis in pigs to by-products from cheese and milk factories on which they were experimentally fed. Our continental competitors, especially in Germany and Denmark, make it a criminal offence to feed to farm stock even the washings from cream separators unless they have been sterilised, and it is indeed strange that up to the present our agricultural colleges and our biochemists have not taken the matter up from the pathologist's point of view—namely, that the trouble is not so much due to infection and unhygienic conditions as to the lowered resistance of the dairy cow to tuberculosis as the results of unnatural feeding.—I am, Sir, yours faithfully,

M. J. ROWLANDS, M.D.

FUNDAMENTAL CANCER KNOWLEDGE.

To the Editor of THE LANCET.

SIR,—In the leading article with this title in your issue of August 9th you show that, as a result of many years of arduous research, a foundation for the hoped-for superstructure has been laid. There is, however, a missing stone. Work on this problem was started at a period when the connexion between preventive medicine, mobile laboratories, and stationary investigation laboratories was but little recognised. Thus research was commenced and has been continued by the pathologist, aided by clinical observation and ever-increasing biochemical knowledge. In the present day, were a new disease to attract attention, concerning the nature of which various observers differed in details but were on common ground in asserting that (1) it appeared at a certain period of life, (2) was apt to be found (*a*) in users of special diets, (*b*) in successive inhabitants of certain houses, (*c*) in places haunted by rodents and wasteful, and itself in need of first-aid. (2) A system that leaves the treatment of the mass of tuberculous persons at the stage where the patient returns to almost certain relapse and spread of infection to others, is unsound and even inhuman. (3) We cannot wait, as some would have us do, for general hygienic, social and economic improvements to suppress the disease but make a direct frontal attack on its infectivity.

I believe I have made out a case for inquiry, when further data can be obtained and details worked out.

UNIVERSITY OF LONDON BY-ELECTION.

NOMINATIONS for the seat left vacant by the death of Sir Sydney Russell-Wells must be received by the returning officer before 11 A.M. on Oct. 1st. Polling takes place from Oct. 13th to 17th by voting papers sent to all graduates on the Parliamentary Register. At present three candidates are known to be standing.

Sir **JOHN ROSE BRADFORD**, official Conservative candidate, has been closely associated with the University and its work for over 40 years as a member of the Senate, an examiner for the University, and until recently a teacher in one of the medical schools. He was at one time secretary of the Royal Society, and he served throughout the war as consulting physician to the British Expeditionary Force in France. He stands for: (1) the maintenance of external degrees in all faculties; (2) a Senate on which graduates and teachers are fully represented: (3) freedom of the University from State control; (4) development of the full resources of the University both on its internal and external sides; (5) the maintenance of the degrees of the University at their undisputed standard; (6) the improvement of the status and responsibility of the teacher; (7) the maintenance and increase of all facilities for the progress of boys and girls from school to the University. In order to carry out these aims he regards it as essential that the Governing Body or Senate should be of a representative character and contain representatives in adequate numbers of the teachers and of the graduates. He is opposed to the conception of a nominated Senate, or to any policy that would restrict the present share of representation of graduates and teachers on the Governing Body. He is opposed to the appointment of any statutory commission, more especially if empowered to carry out recommendations that would result in giving the University a nominated as opposed to a representative Senate, or in restricting the proportionate representation of teachers and graduates. Should Mr. Trevelyan carry out his intention of appointing a departmental committee to consider and report on the development of the University, he would exert his influence to see that all aspects were fully considered. Such changes as may be needed would, he believes, affect in the main the internal side of the University. He would support and advocate means by which the University may render greater assistance than it does at present to the student who, because of want of means or other hindrance, cannot obtain teaching in London or elsewhere. The two sides of the University must, he states, be fully developed if it is to play its proper part as an Imperial and as a metropolitan university. He is not pledged to any site for the University.

Dr. **E. GRAHAM LITTLE** is standing as a Non-Political candidate with the support of the Graduates' Association, which has consistently fought the recommendations of the Haldane Commission. Having had 18 years' experience of the administrative work of the University as member of the Senate, he considers that sufficient time has not yet been allowed for testing the quality and permanence of the Dual Constitution imposed in 1900. Left to themselves the two sides of the University could readily come to an agreed decision. If elected he means to fight for certain principles threatened by the Haldane Report—namely, (1) freedom of the University from bureaucratic control; (2) government of the University by its graduates and teachers; (3) maintenance of external degrees; (4) preserving the present relations between the secondary schools and the University; (5) free and harmonious development of both sides of the University and the continuous expansion of the field of its activities; (6) conservation of the standard of the degrees, and of the central control by the University of degree-giving examinations. As chairman of the Council for External Students he clings to the uniquely Imperial character and functions of the University as the only one whose examinations can be taken in all parts of the Empire. He will oppose any change that would lower the historic standard, not only in justice to those who have obtained the earlier degrees, but because of the damage to prestige. He would exact the fullest consultation of the faculty concerned before any action affecting that faculty is taken by the Senate. He desires to see the University continuing to provide, as it has done throughout its past, the best educational opportunities for the largest number of people.

Prof. **A. F. POLLARD**, who is standing as Liberal candidate, is the founder of the Institute of Historical Research, open to all graduates duly qualified, whether internal or external; and was chairman of the Board of Studies in History when it successfully recommended the Senate to establish there a special adviser to external students. The University, like all living and growing organisms, may need modification and greater elasticity to adapt itself to expanding needs and fresh responsibilities, but all schismatic proposals to separate the internal from the external side or research from teaching seem to him fraught with disaster. The latest and momentous developments of the University have been achieved by hearty coöperation between representatives of different interests. The old examining side of the University, he feels, did invaluable work in nursing the newer universities into existence before any one of them was strong enough to stand on its own feet. There will, he is sure, long continue to be growing centres of education looking to London for a means and a standard of examination, as well as individual students outside the area of any university or university college who would be debarred from a degree but for the University of London. At the same time, the ultimate aim of a university is to provide a university education, and the existence of 10 millions of people within the area of the University of London imposes upon it an enormous responsibility. It is not merely or mainly a question of examinations and degrees; it is, Prof. Pollard holds, an exploded anachronism to think that a university has only to teach the young. There are hundreds of thousands of adults capable and desirous of profiting by the information and inspiration which only a university can provide. He regards it as the prime duty of the University to keep in touch with those who have taken its degrees and to get into touch with those who have not, but who live within its sphere of influence and wish to avail themselves of its facilities.

MANCHESTER ROYAL INFIRMARY.—Post-graduate lectures will be given this year on the same lines as those given during the past few years. Till Christmas these will be given twice weekly, on Tuesdays and Fridays at 4.15 P.M. All medical men are cordially invited to attend. During the last two years four professors at the Manchester University closely connected with the teaching of medical students—viz., Profs. J. S. B. Stopford, H. S. Raper, R. B. Wild, and W. H. Bragg—have been appointed respectively honorary advisory anatomist, physiologist, pharmacologist, and physicist to the Royal Infirmary. This step has helped to bring the University and the Royal Infirmary, the two largest constituents of the medical school, more closely in touch. Three of these professors (Prof. Bragg is still in America) are joining in the Friday post-graduate lectures, which are generally more scientific in type than those given on Tuesdays. On Oct. 7th, instead of the usual lecture, Sir John Bland-Sutton will give the Lloyd Roberts lecture, and has chosen the subject of Attic Salt for Gall-stones. It has been decided in Manchester, as in London, to give only one Lloyd Roberts lecture yearly. This year it will be at the Royal Infirmary, next year at the St. Mary's Hospitals.

examination of their microscopic structure. But there are great difficulties still to be overcome. I have myself been studying the gross and microscopic appearances of tumours for the past 40 years. Yet I often meet with a microscopic section which to my knowledge does not fall into any of the routine groups. After a period of speculation and research I am sometimes able to recognise its true nature by comparison with a similar specimen in my collection. At other times the nebulous picture of a similar specimen seen somewhere years before will not materialise and I am left in uncertainty. In the museum all the specimens would be catalogued and classified in such a manner that anyone could rapidly pick out that case which corresponded with the one under review.

The following case—one of many—is typical of the difficulties which I have observed in my own professional experience:—Tumour of forearm: (1) Report by E. H. S., "the Tumour is a lymphadenoma and is malignant"; (2) report by Dr. B., "Fibrosarcoma, possesses local malignancy not recurring after adequate removal"; (3) report of Mr. C., "Lymphangioma. No malignant transformation has occurred." The surgeon who removed the tumour was thus left to ponder the above reports, clearly at variance.

Two more outstanding advantages of a National Pathology Museum declare themselves: (1) The provision of more and better-trained pathologists (by reason of the fact that students will find knowledge ready to their hands instead of requiring years of experience to acquire); and (2) the centralising and rendering permanent of the vast stores of information and experience which pathologists up and down the country have gained and much of which will eventually die with them unless some means such as this is devised for its preservation.

The only objection raised is that of finance. Many physicians and surgeons have expressed interest in this scheme, but all point out that the proposed museum would cost a lot of money. How can this money be obtained? The medical profession cannot afford it. The State is already overburdened. We must look elsewhere and hope that some generous individual will come forward and found an institution which would fill a great need.

I am, Sir, yours faithfully,

ERNEST H. SHAW, M.R.C.P. Lond.

Royal Northern Hospital, London, N.,
Sept. 20th, 1924.

PROVISION FOR RHEUMATIC CHILDREN IN BIRMINGHAM.

To the Editor of THE LANCET.

SIR,—In connexion with your leading article of August 28th on Rheumatic Affections in Children, you kindly refer to one portion of the attempt which is being made to deal with this problem in Birmingham: perhaps I may be allowed to draw attention to other work of a similar character which is being carried out by the City of Birmingham Education Committee through its Special Schools Department, which is mentioned in another portion of the annual report from which you quote. Baskerville House Residential School for Physically Defective Children has 47 beds, the majority of which are devoted to children who suffer from rheumatic affections and intractable chorea. During the past three years just over 100 children have been in residence under observation for an average period of six months. Dr. A. P. Thomson, Special Schools Medical Officer, writes:—

> "The majority of the children in Baskerville have some form of rheumatic disease. Sufficient time has hardly elapsed to enable me to speak definitely of the results, but the first re-examination of children who had left the school six months or more previously was very promising; most of them had been in good health and in regular attendance at an elementary school, whereas before their admission they had either been entirely absent from school for some years or had attended only sporadically. I wish to point out that we find at Baskerville that suitably controlled educational methods are a very valuable adjunct in the treatment of rheumatic (and especially choreic) children.
>
> "During the year I have been endeavouring to discover tests by the use of which it would be possible to be sure that a child had become safe from the danger of rheumatic relapse or the further progress of disease of the heart. . . .
>
> "We found that as a whole the children did not do well during the winter term and we thought it possible that the absence of sunlight might be of importance in predisposing to relapse. We propose to use an ultra-violet lamp in the future during the sunless periods."

In addition to the above, an attempt is being made, in connexion with a committee of the British Medical Association, to study the geographical and seasonal distribution of rheumatic affections. The names of all children who are reported as unable to attend school on this account by private practitioners, school medical officers and school nurses, school attendance officers and health visitors, are collated and, as far as possible, investigated. In this way it is hoped that material of real value towards the elucidation of ætiology, treatment, and educational procedure will be forthcoming.

I am, Sir, yours faithfully,

G. A. AUDEN.

Sept. 20th, 1924. School Medical Officer, Birmingham.

INCIDENCE OF GOITRE IN EGYPT.

To the Editor of THE LANCET.

SIR.—In the paper on the above subject which appeared in THE LANCET of Sept. 13th, the authors, Prof. R. V. Dolbey and Dr. M. Omar, of Cairo, state that they have been informed that there is no goitre in Abyssinia, and that they have seen none in the Sudan. So far as Abyssinia is concerned, the information furnished them would appear to be incorrect, as they will find on reference to an interesting paper by Dr. Charles Singer on Notes on Cases met with in South-Western Abyssinia in March, 1904, which appeared in the *Journal of Tropical Medicine* for 1905 (p. 17). In this paper Dr. Singer states that

> "Cases of goitre were met with throughout our route across Abyssinia, but were much more common in the western than in the eastern part. The cases were usually of a parenchymatous type, but adenomatous and other forms were met with, and Graves's disease seemed far from rare. All the cases of goitre that I saw were in the plateau itself, and I saw none in the low country forming the valley of the Sobat and Baro rivers, which are inhabited by Negro tribes of quite different race to the Gallas and Abyssinians of the high country."

Possibly Prof. Dolbey and Dr. Omar had in mind only the low country to which Dr. Singer refers, as this is the part traversed by the Sobat and Baro, which are large and important tributaries of the White Nile. It should, however, be noted that goitre does occur, and is indeed common in the South-Western portions of Abyssinia. Whether the disease is also met with on the northern part bordering on Lake Tsana, the source of the Blue Nile, I am unable to say.

I am, Sir, yours faithfully,

ANDREW BALFOUR.

London School of Hygiene and Tropical
Medicine, Sept. 22nd, 1924.

WORTHING HOSPITAL, SUSSEX.—This excellently managed hospital is one of 46 beds: the governors are hoping in the near future to bring that number up to 100. In the spring of last year a new wing was opened providing for maternity and paying patients, but still the provision is inadequate. Thanks to the balance in hand of £666 at the end of the last financial year and the receipt since Jan. 1st last of £2700 in legacies and life governors' subscriptions, the governors at their meeting decided to proceed at once with a scheme for the rebuilding of the administrative departments and the reconstruction of the heating and hot-water systems, at a cost in round figures of £5000. The difference between the sums of £2700 and £5000 is to be taken from capital as required. Land immediately to the north of the new maternity wing is to be utilised for the purposes of the new departments, and the plans have been so prepared that the new works may harmonise with the still larger developments which are in contemplation. In the present scheme the most pressing need is the reconstruction of the domestic offices: while in the past considerable difficulty has been experienced in keeping the institution warm. The first buildings of the present hospital were opened in 1881, but it was in 1829 that hospital work was begun in the town in two rooms.

their concomitant food and parasites, (*d*) in human subjects of helminthism, (*e*) in persons following occupations involving contact with chemicals—field work probably would (and certainly should) be the first effort towards disentanglement of reputed factors.

An area where prevalence of the disease was on the increase having been selected, a house-to-house inquiry by the sanitarian, aided by experts in the various sciences dealing with life factors, as influenced by the environment of man and beast, would be conducted. This would embrace in detail the history, in reference to these factors, of both the healthy and the diseased in each house within the selected area. The toil would be great, but would be trivial compared with the 24 years' research by pathologists thus unaided in the quest of truth. The British Empire Cancer Campaign has recently set up committees for statistical and economic research into the causation of cancer. What I should like to see would be carefully recorded details (say) of a thousand households devoid of effort to support a particular theory, which would afford, on concentration, a mathematical basis on which to apportion the guilt of suspect causative agents. Such a method led Sir Ronald Ross, 25 years ago, to put aside hypothesis in malaria research and confine labour to immediate factors. An inquiry of this kind would be hopelessly handicapped in Great Britain, where the analogues of Hindu caste and the American Munroe doctrines guard the Englishman's home. But in tropical and subtropical countries there are known to be cancer-affected and, possibly, cancer-free areas where indigenous races less likely to resent intimate inquiries are to be found—as shown by the success of the Rockefeller anti-hookworm campaign. The funds now available for cancer research would not be unduly depleted by outlay on "expeditions," for pursuit of this practically untouched branch of an important subject.—I am, Sir, yours faithfully,

W. G. KING,
London, N.W., Sept. 17th, 1924. Colonel, I.M.S. (ret.).

WANTED, A JOURNAL OF MECHANO-THERAPEUTICS.

To the Editor of THE LANCET.

SIR,—It is practically the rule that as soon as any particular branch of medical or surgical science comes to be regarded as a specialty, journals devoted to it commence to appear in various languages. Before long the only possible complaint is that there are too many of such publications. There is, however, one notable exception—viz., mechano-therapeutics, to which (together with its forerunner and foundation—namely, educational gymnastics) there are only four small journals exclusively devoted. These are: 1. *Svenska Gymnastiken i Utlandet* (Swedish Gymnastics Abroad), founded 1905. 2. *Tidskrift i Gymnastik* (Journal of Gymnastics), founded 1873, published respectively by the International and Swedish Societies of Graduates of the Royal Central Gymnastic Institute of Stockholm. Both these periodicals are in the Swedish language, and only the former reviews the literature systematically. 3. *Journal of the Chartered Society of Massage and Medical Gymnastics*. 4. *Maandschrift voor Heilgymnastiek*, the official publication of the Dutch Society for Medical Gymnastics and Massage. Apart from these, the only medical journals that consistently devote any space to mechano-therapeutics are the *Zeitschrift für orthopädische Chirurgie* and the *Archiv für Orthopädie*, which review the literature in so far as it is related to orthopædics, and the *Zeitschrift für die gesammte Physikalische Therapie*, which deals with physical therapeutics as a whole.

What is needed at the present day is a Journal of Mechano-Therapeutics which would publish original articles and reviews of current literature on all branches of the movement cure, such as massage proper, vibration, passive and active movements of joints, "manipulative surgery," "remedial exercises," "spondylotherapy," and all portions of educational gymnastics and physical drill that have for their object the prevention or cure of disease or which are the foundation of therapeutic movements. The appearance of such a journal would supply a long-felt want, and be welcomed by the medical men interested in these methods whose number increases year by year, and I see no reason why England should leave it to the foreigner to take the first step.—I am, Sir, yours faithfully,

EDGAR F. CYRIAX.
Welbeck-street, W., Sept. 20th, 1924.

THE TISSUE PATHOLOGIST.

To the Editor of THE LANCET.

SIR,—I was keenly interested in a leading article in THE LANCET of Sept. 6th on the tissue pathologist. Last year [1] when drawing attention to the scarcity of pathologists who have a wide knowledge of morbid anatomy and histology, I briefly outlined a scheme for the formation of a National Pathological Museum which would stimulate the study of this branch of our profession and in course of time become a valuable training centre for future pathologists.

Briefly the scheme is as follows:—

1. A building in a central position, such as the Museum of the Royal College of Surgeons of England.
2. A governing body composed of, say, representatives of the various Colleges and Universities. (To include surgeons, physicians, pathologists, &c.)
3. An executive staff of medical men: (*a*) a pathologist (the head of the Institute) and possibly an assistant pathologist; (*b*) bacteriologist; (*c*) embryologist; (*d*) comparative anatomist, perhaps also a chemist and others.
4. Working staff to do section cutting, mounting, specimen and clerical work; artists and photographers should be included. This organisation and staff would be responsible for the important work of the institution itself, but there would remain the problem of relating the work of the museum to the practice of the surgeon in every part of the country. The actual practical results to be secured from it would be so immediate, the knowledge to be gained so far-reaching, that much could be accomplished towards compiling what I may term a finger-print system of malignant disease comparisons.

To ensure that such an institution would be supplied with suitable and adequate material the coöperation of practitioners and medical schools throughout the country would be required. For this purpose I would propose the appointment of agents or scouts, in connexion with the medical schools. The inducement I would present would be the offer of a certain number of scholarships to young people desirous of taking up the career of pathology. In this way two valuable purposes would be secured: (1) Students would be constantly on the watch for material obtained, as it were, at first hand with which to supply the centre. (2) They would be gaining valuable experience and the ranks of first-class morbid anatomists would be strengthened.

Yet a further advantage discloses itself. The sum of human knowledge would be considerably added to if in certain classes of tumour the after-history of patients could be carefully noted and compared. The authorities of the museum would be charged to give immediate notice of any such cases which came to their notice, and to supply forms for, and details of, the information which they required. I believe there are very few practitioners in this country who would not readily collaborate in such work; especially where, as I am perfectly assured would very quickly be the case, the national pathological museum began to give practical demonstration of its work.

The results of the work carried on by the staff of the museum would be made known to the profession through the usual channels, and, in addition, its activities might well include the publication, from time to time, of an Atlas of Pathology. Thus eventually we should secure a standard by means of which the tumours of every class could be at once recognised and properly placed, and a correct diagnosis and prognosis given.

The need which exists for the formation of such a museum, and the results which would accrue from it, require only brief statement at present. The great majority of tumours found at operation are easily placed in their right category on

examination of their microscopic structure. But there are great difficulties still to be overcome. I have myself been studying the gross and microscopic appearances of tumours for the past 40 years. Yet I often meet with a microscopic section which to my knowledge does not fall into any of the routine groups. After a period of speculation and research I am sometimes able to recognise its true nature by comparison with a similar specimen in my collection. At other times the nebulous picture of a similar specimen seen somewhere years before will not materialise and I am left in uncertainty. In the museum all the specimens would be catalogued and classified in such a manner that anyone could rapidly pick out that case which corresponded with the one under review.

---

[1] THE LANCET, 1923, i., 218.

The following case—one of many—is typical of the difficulties which I have observed in my own professional experience:—Tumour of forearm: (1) Report by E. H. S., "the Tumour is a lymphadenoma and is malignant"; (2) report by Dr. B., "Fibrosarcoma, possesses local malignancy not recurring after adequate removal"; (3) report of Mr. C., "Lymphangioma. *No malignant transformation* has occurred." The surgeon who removed the tumour was thus left to ponder the above reports, clearly at variance.

Two more outstanding advantages of a National Pathology Museum declare themselves: (1) The provision of more and better-trained pathologists (by reason of the fact that students will find knowledge ready to their hands instead of requiring years of experience to acquire); and (2) the centralising and rendering permanent of the vast stores of information and experience which pathologists up and down the country have gained and much of which will eventually die with them unless some means such as this is devised for its preservation.

The only objection raised is that of finance. Many physicians and surgeons have expressed interest in this scheme, but all point out that the proposed museum would cost a lot of money. How can this money be obtained? The medical profession cannot afford it. The State is already overburdened. We must look elsewhere and hope that some generous individual will come forward and found an institution which would fill a great need.

I am, Sir, yours faithfully,
ERNEST H. SHAW, M.R.C.P. Lond.

PROVISION FOR RHEUMATIC CHILDREN IN BIRMINGHAM.

To the Editor of THE LANCET.

SIR,—In connexion with your leading article of August 28th on Rheumatic Affections in Children, you kindly refer to one portion of the attempt which is being made to deal with this problem in Birmingham; perhaps I may be allowed to draw attention to other work of a similar character which is being carried out by the City of Birmingham Education Committee through its Special Schools Department, which is mentioned in another portion of the annual report from which you quote. Baskerville House Residential School for Physically Defective Children has 47 beds, the majority of which are devoted to children who suffer from rheumatic affections and intractable chorea. During the past three years just over 100 children have been in residence under observation for an average period of six months. Dr. A. P. Thomson, Special Schools Medical Officer, writes:—

> "The majority of the children in Baskerville have some form of rheumatic disease. Sufficient time has hardly elapsed to enable me to speak definitely of the results, but the first re-examination of children who had left the school six months or more previously was very promising; most of them had been in good health and in regular attendance at an elementary school, whereas before their admission they had either been entirely absent from school for some years or had attended only sporadically. I wish to point out that we find at Baskerville that suitably controlled educational methods are a very valuable adjunct in the treatment of rheumatic (and especially choreic) children.
>
> "During the year I have been endeavouring to discover tests by the use of which it would be possible to be sure that a child had become safe from the danger of rheumatic relapse or the further progress of disease of the heart. . . .
>
> "We found that as a whole the children did not do well during the winter term and we thought it possible that the absence of sunlight might be of importance in predisposing to relapse. We propose to use an ultra-violet lamp in the future during the sunless periods."

In addition to the above, an attempt is being made, in connexion with a committee of the British Medical Association, to study the geographical and seasonal distribution of rheumatic affections. The names of all children who are reported as unable to attend school on this account by private practitioners, school medical officers and school nurses, school attendance officers and health visitors, are collated and, as far as possible, investigated. In this way it is hoped that material of real value towards the elucidation of ætiology, treatment, and educational procedure will be forthcoming.

I am, Sir, yours faithfully,
G. A. AUDEN,
Sept. 20th, 1924. School Medical Officer, Birmingham.

INCIDENCE OF GOITRE IN EGYPT.

To the Editor of THE LANCET.

SIR,—In the paper on the above subject which appeared in THE LANCET of Sept. 13th, the authors, Prof. R. V. Dolbey and Dr. M. Omar, of Cairo, state that they have been informed that there is no goitre in Abyssinia, and that they have seen none in the Sudan. So far as Abyssinia is concerned, the information furnished them would appear to be incorrect, as they will find on reference to an interesting paper by Dr. Charles Singer on Notes on Cases met with in South-Western Abyssinia in March, 1904, which appeared in the *Journal of Tropical Medicine* for 1905 (p. 17). In this paper Dr. Singer states that

> "Cases of goitre were met with throughout our route across Abyssinia, but were much more common in the western than in the eastern part. The cases were usually of a parenchymatous type, but adenomatous and other forms were met with, and Graves's disease seemed far from rare. All the cases of goitre that I saw were in the plateau itself, and I saw none in the low country forming the valley of the Sobat and Baro rivers, which are inhabited by Negro tribes of quite different race to the Gallas and Abyssinians of the high country."

Possibly Prof. Dolbey and Dr. Omar had in mind only the low country to which Dr. Singer refers, as this is the part traversed by the Sobat and Baro, which are large and important tributaries of the White Nile. It should, however, be noted that goitre does occur, and is indeed common in the South-Western portions of Abyssinia. Whether the disease is also met with on the northern part bordering on Lake Tsana, the source of the Blue Nile, I am unable to say.

I am, Sir, yours faithfully,
ANDREW BALFOUR.

London School of Hygiene and Tropical
Medicine, Sept. 22nd, 1924.

WORTHING HOSPITAL, SUSSEX.—This excellently managed hospital is one of 46 beds; the governors are hoping in the near future to bring that number up to 100. In the spring of last year a new wing was opened providing for maternity and paying patients, but still the provision is inadequate. Thanks to the balance in hand of £666 at the end of the last financial year and the receipt since Jan. 1st last of £2700 in legacies and life governors' subscriptions, the governors at their meeting decided to proceed at once with a scheme for the rebuilding of the administrative departments and the reconstruction of the heating and hot-water systems, at a cost in round figures of £5000. The difference between the sums of £2700 and £5000 is to be taken from capital as required. Land immediately to the north of the new maternity wing is to be utilised for the purposes of the new departments, and the plans have been so prepared that the new works may harmonise with the still larger developments which are in contemplation. In the present scheme the most pressing need is the reconstruction of the domestic offices; while in the past considerable difficulty has been experienced in keeping the institution warm. The first buildings of the present hospital were opened in 1881, but it was in 1829 that hospital work was begun in the town in two rooms.

their concomitant food and parasites, (*d*) in human subjects of helminthism, (*e*) in persons following occupations involving contact with chemicals—field work probably would (and certainly should) be the first effort towards disentanglement of reputed factors.

An area where prevalence of the disease was on the increase having been selected, a house-to-house inquiry by the sanitarian, aided by experts in the various sciences dealing with life factors, as influenced by the environment of man and beast, would be conducted. This would embrace in detail the history, in reference to these factors, of both the healthy and the diseased in each house within the selected area. The toil would be great, but would be trivial compared with the 24 years' research by pathologists thus unaided in the quest of truth. The British Empire Cancer Campaign has recently set up committees for statistical and economic research into the causation of cancer. What I should like to see would be carefully recorded details (say) of a thousand households devoid of effort to support a particular theory, which would afford, on concentration, a mathematical basis on which to apportion the guilt of suspect causative agents. Such a method led Sir Ronald Ross, 25 years ago, to put aside hypothesis in malaria research and confine labour to immediate factors. An inquiry of this kind would be hopelessly handicapped in Great Britain, where the analogues of Hindu caste and the American Munroe doctrines guard the Englishman's home. But in tropical and subtropical countries there are known to be cancer-affected and, possibly, cancer-free areas where indigenous races less likely to resent intimate inquiries are to be found—as shown by the success of the Rockefeller anti-hookworm campaign. The funds now available for cancer research would not be unduly depleted by outlay on "expeditions," for pursuit of this practically untouched branch of an important subject.—I am, Sir, yours faithfully,

W. G. KING,

London, N.W., Sept. 17th, 1924. Colonel, I.M.S. (ret.).

WANTED, A JOURNAL OF MECHANO-THERAPEUTICS.

To the Editor of THE LANCET.

SIR,—It is practically the rule that as soon as any particular branch of medical or surgical science comes to be regarded as a specialty, journals devoted to it commence to appear in various languages. Before long the only possible complaint is that there are too many of such publications. There is, however, one notable exception—viz., mechano-therapeutics, to which (together with its forerunner and foundation—namely, educational gymnastics) there are only four small journals exclusively devoted. These are: 1. *Svenska Gymnastiken i Utlandet* (Swedish Gymnastics Abroad), founded 1905. 2. *Tidskrift i Gymnastik* (Journal of Gymnastics), founded 1873, published respectively by the International and Swedish Societies of Graduates of the Royal Central Gymnastic Institute of Stockholm. Both these periodicals are in the Swedish language, and only the former reviews the literature systematically. 3. *Journal of the Chartered Society of Massage and Medical Gymnastics.* 4. *Maandschrift voor Heilgymnastiek*, the official publication of the Dutch Society for Medical Gymnastics and Massage. Apart from these, the only medical journals that consistently devote any space to mechano-therapeutics are the *Zeitschrift für orthopädische Chirurgie* and the *Archiv für Orthopädie*, which review the literature in so far as it is related to orthopædics, and the *Zeitschrift für die gesammte Physikalische Therapie*, which deals with physical therapeutics as a whole.

What is needed at the present day is a Journal of Mechano-Therapeutics which would publish original articles and reviews of current literature on all branches of the movement cure, such as massage proper, vibration, passive and active movements of joints, "manipulative surgery," "remedial exercises," "spondylotherapy," and all portions of educational gymnastics and physical drill that have for their object the prevention or cure of disease or which are the foundation of therapeutic movements. The appearance of such a journal would supply a long-felt want, and be welcomed by the medical men interested in these methods whose number increases year by year, and I see no reason why England should leave it to the foreigner to take the first step.—I am, Sir, yours faithfully,

EDGAR F. CYRIAX.

Welbeck-street, W., Sept. 20th, 1924.

THE TISSUE PATHOLOGIST.

To the Editor of THE LANCET.

SIR,—I was keenly interested in a leading article in THE LANCET of Sept. 6th on the tissue pathologist. Last year [1] when drawing attention to the scarcity of pathologists who have a wide knowledge of morbid anatomy and histology, I briefly outlined a scheme for the formation of a National Pathological Museum which would stimulate the study of this branch of our profession and in course of time become a valuable training centre for future pathologists.

Briefly the scheme is as follows:—

1. A building in a central position, such as the Museum of the Royal College of Surgeons of England.
2. A governing body composed of, say, representatives of the various Colleges and Universities. (To include surgeons, physicians, pathologists, &c.)
3. An executive staff of medical men: (*a*) a pathologist (the head of the Institute) and possibly an assistant pathologist; (*b*) bacteriologist; (*c*) embryologist; (*d*) comparative anatomist, perhaps also a chemist and others.
4. Working staff to do section cutting, mounting, specimen and clerical work; artists and photographers should be included. This organisation and staff would be responsible for the important work of the institution itself, but there would remain the problem of relating the work of the museum to the practice of the surgeon in every part of the country. The actual practical results to be secured from it would be so immediate, the knowledge to be gained so far-reaching, that much could be accomplished towards compiling what I may term a finger-print system of malignant disease comparisons.

To ensure that such an institution would be supplied with suitable and adequate material the coöperation of practitioners and medical schools throughout the country would be required. For this purpose I would propose the appointment of agents or scouts, in connexion with the medical schools. The inducement I would present would be the offer of a certain number of scholarships to young people desirous of taking up the career of pathology. In this way two valuable purposes would be secured: (1) Students would be constantly on the watch for material obtained, as it were, at first hand with which to supply the centre. (2) They would be gaining valuable experience and the ranks of first-class morbid anatomists would be strengthened.

Yet a further advantage discloses itself. The sum of human knowledge would be considerably added to if in certain classes of tumour the after-history of patients could be carefully noted and compared. The authorities of the museum would be charged to give immediate notice of any such cases which came to their notice, and to supply forms for, and details of, the information which they required. I believe there are very few practitioners in this country who would not readily collaborate in such work; especially where, as I am perfectly assured would very quickly be the case, the national pathological museum began to give practical demonstration of its work.

The results of the work carried on by the staff of the museum would be made known to the profession through the usual channels, and, in addition, its activities might well include the publication, from time to time, of an Atlas of Pathology. Thus eventually we should secure a standard by means of which the tumours of every class could be at once recognised and properly placed, and a correct diagnosis and prognosis given.

The need which exists for the formation of such a museum, and the results which would accrue from it, require only brief statement at present. The great majority of tumours found at operation are easily placed in their right category on

examination of their microscopic structure. But there are great difficulties still to be overcome. I have myself been studying the gross and microscopic appearances of tumours for the past 40 years. Yet I often meet with a microscopic section which to my knowledge does not fall into any of the routine groups. After a period of speculation and research I am sometimes able to recognise its true nature by comparison with a similar specimen in my collection. At other times the nebulous picture of a similar specimen seen somewhere years before will not materialise and I am left in uncertainty. In the museum all the specimens would be catalogued and classified in such a manner that anyone could rapidly pick out that case which corresponded with the one under review.

---

[1] THE LANCET, 1923, i., 218.

The following case—one of many—is typical of the difficulties which I have observed in my own professional experience:—Tumour of forearm: (1) Report by E. H. S., "the Tumour is a lymphadenoma and is malignant"; (2) report by Dr. B., "Fibrosarcoma, possesses local malignancy not recurring after adequate removal"; (3) report of Mr. C., "Lymphangioma. No malignant transformation has occurred." The surgeon who removed the tumour was thus left to ponder the above reports, clearly at variance.

Two more outstanding advantages of a National Pathology Museum declare themselves: (1) The provision of more and better-trained pathologists (by reason of the fact that students will find knowledge ready to their hands instead of requiring years of experience to acquire); and (2) the centralising and rendering permanent of the vast stores of information and experience which pathologists up and down the country have gained and much of which will eventually die with them unless some means such as this is devised for its preservation.

The only objection raised is that of finance. Many physicians and surgeons have expressed interest in this scheme, but all point out that the proposed museum would cost a lot of money. How can this money be obtained? The medical profession cannot afford it. The State is already overburdened. We must look elsewhere and hope that some generous individual will come forward and found an institution which would fill a great need.

ANDREW BALFOUR.

London School of Hygiene and Tropical
Medicine, Sept. 22nd, 1924.

WORTHING HOSPITAL, SUSSEX.—This excellently managed hospital is one of 46 beds; the governors are hoping in the near future to bring that number up to 100. In the spring of last year a new wing was opened providing for maternity and paying patients, but still the provision is inadequate. Thanks to the balance in hand of £666 at the end of the last financial year and the receipt since Jan. 1st last of £2700 in legacies and life governors' subscriptions, the governors at their meeting decided to proceed at once with a scheme for the rebuilding of the administrative departments and the reconstruction of the heating and hot-water systems, at a cost in round figures of £5000. The difference between the sums of £2700 and £5000 is to be taken from capital as required. Land immediately to the north of the new maternity wing is to be utilised for the purposes of the new departments, and the plans have been so prepared that the new works may harmonise with the still larger developments which are in contemplation. In the present scheme the most pressing need is the reconstruction of the domestic offices: while in the past considerable difficulty has been experienced in keeping the institution warm. The first buildings of the present hospital were opened in 1881, but it was in 1829 that hospital work was begun in the town in two rooms.

politan borough of St. Pancras and the county boroughs of Barnsley, Leeds, Leicester, Sheffield, and Oxford. On three separate occasions this year a single case of the disease has been notified from different metropolitan boroughs. There is no evidence of the presence of small-pox in London at the present time.

Although generally the type of disease continues to be mild, severe cases occur from time to time; in the Willesden urban district in June-July there were ten cases, with three deaths.

SCHOOL MEDICAL SERVICE.

Cardiff.

THE school medical officer for Cardiff, in his report for the year 1923, states that the appointment of an additional medical officer has enabled the authority to cope with the extra work entailed in the extension of the city boundaries in 1922. During the year much attention has been paid to the question of the crippled child. In 1923 there occurred at least 50 fresh cases of infantile paralysis, many of whom are not in touch with any medical organisation, and will probably become incurable cripples before they reach school age. There are in Cardiff 122 children of school age who have never attended school because of one form or another of physical defect, while a further group of 15 put in no attendances in 1923 up to the end of September, thus making a total of 137 whose education as far as public provision is concerned is entirely in abeyance. Altogether in 1923 there were 530 children medically certified as physically defective, 500 of whom require special accommodation. Dr. Ralph M. F. Picken points out that Cardiff is unique among cities in the extent of open space remaining in or near its centre, and suggests the advisability of having a central situation for all special schools, thereby minimising the difficulties of transport. The total number of elementary school-children examined was 10,740. Of the 13,881 children examined in the routine and special groups, 27 per cent. were found suffering from one or more defects, excluding uncleanliness and dental disease, requiring special treatment. Investigations not yet ready for publication are being carried out with reference to the results of operative treatment of tonsils and adenoids and to the incidence and control of enlargement of the thyroid gland.

Colchester.

Dr. W. F. Corfield reports that a sight-saving class has now been opened in East Ward School. This is an important addition to Colchester's scheme of treatment. The class for stammerers is in abeyance this year owing to the few cases at present suffering from this defect. The children who already have had treatment are visited and urged to practise the methods of treatment they were taught. An additional session is now being given to dental inspection and treatment. The number of children with spinal curvature grows steadily less, and Dr. Corfield attributes this to the particular attention paid to physical training. In 1923 there were 88 children with spinal curvature under treatment either by extra physical drill supervised by a teacher at the school, or for the more severe cases by exercises under the organiser of physical training at a special class arranged for the purpose. By the end of the year 33 cases had been cured and seven had been transferred from the spinal class to their own school classes.

Durham.

This report is always interesting. In spite of the shortage of staff and the amount of work done, Dr. G. C. M. McGonigle, assistant school medical officer, has made a special study of the condition of the thyroid gland in the children who came up for routine medical inspection in a particular part of the county. He found that of a total of 478 boys and girls examined 10·3 per cent. showed definite thyroid enlargement, so that in that part of the Wear Valley which lies above Witton-le-Wear, approximately 1 in 6 of all the children examined have definite enlargement of the thyroid gland. The percentage among boys and girls at the age of 5 was found to be practically equal, but at the ages of 8 and 12 there are approximately twice as many cases among girls as boys. A certain amount of thyroid enlargement is normal and common in adolescent girls, but in a goitrous district the condition is found much more frequently at this age than in a non-goitrous district. The distribution of goitre in Weardale is interesting. Dr. McGonigle found that from the head of the Wear to Wolsingham goitre is common, but below this place it is rare. As such excellent results have been got from treating this condition in its initial stages with sodium iodide the suggestion is made that preventive measures should be taken against goitre in the particular districts affected. The expense of such measures would be trifling and could easily be carried out by the school medical staff. An excellent provisional scheme such as is carried out in certain goitrous districts in Switzerland is suggested. Dr. Eustace Hill reports that an extra medical officer is required to complete the necessary code inspections, and by the appointment of an additional nurse a third school clinic which is urgently needed could be staffed.

Gloucestershire.

Dr. J. Middleton Martin records substantial improvement in the cleanliness of the children, the number of children with dirty heads having been reduced from 25 to 11 per cent. in the last ten years or so. Treatment for defects is also going ahead rapidly. At present the scheme for treatment covers only about one-third of the county, but provisional proposals have been made whereby it can readily be extended to embrace the whole area. Dr. Martin urges that the cost of extending the present arrangements to cover the whole county would be approximately only double the present expense. There is one well-coördinated scheme providing for maternity and child welfare and treatment of school-children. Ten schools in the Cinderford area were closed during the year by order of the district council on account of small-pox, and one of the assistant medical officers, Dr. T. F. Blake, who was released for this purpose from ordinary school work, gave valuable help in connexion with the outbreak by discovering in the schools four missed cases of small-pox.

Leamington Spa.

The number of children examined in the three code groups was 1169. Excluding dental defects and uncleanliness, only 8·7 per cent. of these children were found to have defects requiring medical treatment. There is still, unfortunately, a percentage of 57 of unvaccinated children. Twelve cases of goitre were noted, and in five instances a family history of the disease was recorded.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED SEPT. 13TH, 1924.

Notifications.—The following cases of infectious disease were notified during the week, namely:—Small-pox, 54; scarlet fever, 1600; diphtheria, 733; enteric fever, 120; pneumonia, 443; puerperal fever, 41; cerebro-spinal fever, 9; acute poliomyelitis, 23; acute polio-encephalitis, 3; encephalitis lethargica, 43; typhus fever, 1; dysentery, 2; ophthalmia neonatorum, 123. There were no cases of cholera or plague notified during the week. The case of typhus was again from St. Helens.

Deaths.—In the aggregate of great towns, including London, there were 3 deaths from enteric fever, none from small-pox, 16 from scarlet fever, 22 from diphtheria, 9 from measles, 18 from influenza. In London itself the diphtheria deaths numbered 7, and the deaths from infantile diarrhœa, which had been 22, 25, and 30 in the preceding three weeks, declined to 23. Another death from typhus was registered from St. Helens.

Chicken-pox Notifiable.—Ashton-under-Lyne Town Council, in consequence of an outbreak of small-pox, the first for 17 years, has made chicken-pox a notifiable disease for the next six months. Three cases of small-pox have been reported and all contacts have been revaccinated.

Public Health Services.

THE OUTBREAK OF TYPHUS FEVER IN ST. HELENS.

WE are indebted to Dr. Frank Hauxwell, medical officer of health for St. Helens, for some details of the recent outbreak of typhus in that county borough. The first case was discovered on August 12th. After having been ill at home for nearly a week, a girl, aged 14, was sent to the isolation hospital from 18, Bold-street, on the evening of August 11th, by her own doctor as suffering from measles. When seen next day by a medical officer of the health department typhus was suspected, and this was later confirmed by Dr. W. Hanna, of Liverpool. This child died three days after admission. In following this case up it was found on visiting the home that the father had also been ill at home for nearly a week and was being treated for "influenza." He also proved to be suffering from typhus fever and was removed to hospital on August 13th, where he made a good recovery. In pursuing inquiries further it was found that about a month previously (July 13th) another child from the same house had been taken seriously ill and had been treated in the Providence Hospital for "pneumonia," being discharged well from that hospital on August 10th. From a consideration of the history of this case and from the result of a blood-test taken since, there is no doubt that this also was a case of typhus and, so far as is known, the first case of the present outbreak.

The infection had existed, therefore, in the town for at least a month before it came to the knowledge of the health department. The home of this family is in one of the poorer localities of the town and the bedrooms were very dirty, beds and bedding infested with vermin, as also were many cracks and crevices in the plaster. Structurally the house is not in bad sanitary condition. The sleeping accommodation consisted of two upstairs rooms; father, mother, and baby being accommodated in one bedroom, three children in the other. There were no lodgers nor, so far as could be ascertained, had there been any.

On the day following admission of the father to hospital the whole of the remainder of the family, consisting of the mother and three children—i.e., the immediate contacts—were admitted to hospital with a view to personal cleansing and disinfestation and to allow of thorough cleansing of the house. Bedding and wearing apparel were disinfected by steam. Mattresses, flock beds, and a sofa were found to be so infested with vermin that it was considered advisable to destroy them and compensate the owners. The house itself was thoroughly disinfected by spraying, and by arrangement with the owner the walls and ceilings were stripped and re-covered. Other possible contacts were kept under daily observation by a health visitor. The mother and three children were allowed to return home, having been in hospital for eight days. Dr. Hauxwell points out the difficulty there is in enforcing isolation of contacts; this can only be done by application of the local authority to two justices for a removal order, a proceeding which means delay to such an extent as to nullify its value.

The next case to occur was a child, aged 5, sister of the original case. This child was taken ill on August 28th—i.e., 15 days since the removal of the last case and seven days after discharge from hospital as a contact. She was seen on August 29th by the family doctor, who reserved his opinion; later, on the same day a medical officer of the health department diagnosed typhus and the child was removed to the isolation hospital, where she made a good recovery. On the afternoon of August 30th the mother took to bed because she "felt too weak to walk," and when visited on the next day (31st) was also diagnosed typhus and removed to hospital, where she died on Sept. 8th.

In following up the contacts of these cases a sister-in-law, living at 42, Liverpool-street, who had been in more or less close contact with the family, was found on August 31st to be suffering from the disease. She had been under observation since the commencement of the outbreak, and though visited daily said she was perfectly well, yet when detected she had a temperature of 103° F. and was a well-marked case. She was removed to hospital the same day and died there on Sept. 5th. These three cases illustrate the difficulty experienced in dealing with contacts. They had been seen daily by the health visitor, frequently also by a medical officer, and by the sanitary inspector. No indication was obtainable that they were other than well, and yet they must have been—especially in the last case—ill some days previous to discovery, and only willing afterwards to admit that this was so.

The next case to occur was in one of the contacts under observation, a lad, aged 22, living at 44, Liverpool-street. He was found in the early stage of the disease on Sept. 7th and was removed to hospital the same day. In dealing with these later cases the same procedure was adopted as in the earlier cases. The immediate contacts, so far as possible, were removed to hospital with the hope of keeping them there for at least 21 days so as to cover the incubation period. All other contacts are visited daily. Contacts not admitted to hospital are sent there for a bath and disinfection of clothing. Bedding and clothing are disinfected by steam, mattresses and articles which cannot be disinfected are destroyed and compensation paid. The houses are disinfected and the walls stripped and cleansed. Dr. Hauxwell acknowledges the ready compliance of house owners with his wishes.

Further steps being taken with a view to limiting the spread of the disease are as follows: (*a*) House-to-house visitation in the immediate vicinity by one of the sanitary inspectors; where necessary, disinfection of the house and lime-washing of walls is recommended, lime-wash and brush being supplied for the purpose; if necessary official notice to cleanse under Public Health Act, 1875, Section 46, is served; disinfection of bedding, clothing, and of persons offered wherever advisable. (*b*) Special attention regarding cleanliness to scholars attending schools in the immediate vicinity, since mild or abortive cases are apt to occur in children; inquiry regarding all absentees. (*c*) All cases of illness in the vicinity inquired into as far as possible. (*d*) Issue of leaflet and posters drawing attention to the dangers of the disease and importance of cleanliness in fighting it.

So far there have been eight cases, with four deaths. The last case occurred on Sept. 13th in a boy of 12, who had been detained as a contact at the hospital since Sept. 1st. Ten contacts are at present in hospital and 90 others are under supervision.

SMALL-POX IN ENGLAND AND WALES DURING 1924.

UP to the end of the second week in September small-pox appeared in 91 sanitary (including port) districts, the total number of cases being approximately 2750, as compared with 1840 in the corresponding period of 1923. Derbyshire accounts for 1080 cases in 16 sanitary districts (more than one half in the borough and rural district of Chesterfield); Nottingham for 434 cases in 10 districts. 386 cases occurred in Yorkshire (mainly in Middlesbrough) and 306 in Northumberland (mainly in Ashington).

At the present time small-pox is prevalent in Middlesbrough, Chesterfield, and the urban district of Hucknall, in all of which districts the disease has continued to be present since the autumn of 1923. Other sanitary districts now mainly affected are Derby, Mansfield, the rural district of Chesterfield, and the urban districts of Mansfield Woodhouse, Ashington, Melton Mowbray, and Gainsborough. Within the last four weeks sporadic cases have occurred in 21 other sanitary districts, including the metropolitan borough of St. Pancras and the county boroughs of Barnsley, Leeds, Leicester, Sheffield, and Oxford. On three separate occasions this year a single case of the disease has been notified from different metropolitan boroughs. There is no evidence of the presence of small-pox in London at the present time.

Although generally the type of disease continues to be mild, severe cases occur from time to time; in the Willesden urban district in June-July there were ten cases, with three deaths.

SCHOOL MEDICAL SERVICE.

Cardiff.

THE school medical officer for Cardiff, in his report for the year 1923, states that the appointment of an additional medical officer has enabled the authority to cope with the extra work entailed in the extension of the city boundaries in 1922. During the year much attention has been paid to the question of the crippled child. In 1923 there occurred at least 50 fresh cases of infantile paralysis, many of whom are not in touch with any medical organisation, and will probably become incurable cripples before they reach school age. There are in Cardiff 122 children of school age who have never attended school because of one form or another of physical defect, while a further group of 15 put in no attendances in 1923 up to the end of September, thus making a total of 137 whose education as far as public provision is concerned is entirely in abeyance. Altogether in 1923 there were 530 children medically certified as physically defective, 500 of whom require special accommodation. Dr. Ralph M. F. Picken points out that Cardiff is unique among cities in the extent of open space remaining in or near its centre, and suggests the advisability of having a central situation for all special schools, thereby minimising the difficulties of transport. The total number of elementary school-children examined was 10,740. Of the 13,881 children examined in the routine and special groups, 27 per cent. were found suffering from one or more defects, excluding uncleanliness and dental disease, requiring special treatment. Investigations not yet ready for publication are being carried out with reference to the results of operative treatment of tonsils and adenoids and to the incidence and control of enlargement of the thyroid gland.

Colchester.

Dr. W. F. Corfield reports that a sight-saving class has now been opened in East Ward School. This is an important addition to Colchester's scheme of treatment. The class for stammerers is in abeyance this year owing to the few cases at present suffering from this defect. The children who already have had treatment are visited and urged to practise the methods of treatment they were taught. An additional session is now being given to dental inspection and treatment. The number of children with spinal curvature grows steadily less, and Dr. Corfield attributes this to the particular attention paid to physical training. In 1923 there were 88 children with spinal curvature under treatment either by extra physical drill supervised by a teacher at the school, or for the more severe cases by exercises under the organiser of physical training at a special class arranged for the purpose. By the end of the year 33 cases had been cured and seven had been transferred from the spinal class to their own school classes.

Durham.

This report is always interesting. In spite of the shortage of staff and the amount of work done, Dr. G. C. M. McGonigle, assistant school medical officer, has made a special study of the condition of the thyroid gland in the children who came up for routine medical inspection in a particular part of the county. He found that of a total of 478 boys and girls examined 16·3 per cent. showed definite thyroid enlargement, so that in that part of the Wear Valley which lies above Witton-le-Wear, approximately 1 in 6 of all the children examined have definite enlargement of the thyroid gland. The percentage among boys and girls at the age of 5 was found to be practically equal, but at the ages of 8 and 12 there are approximately twice as many cases among girls as boys. A certain amount of thyroid enlargement is normal and common in adolescent girls, but in a goitrous district the condition is found much more frequently at this age than in a non-goitrous district. The distribution of goitre in Weardale is interesting. Dr. McGonigle found that from the head of the Wear to Wolsingham goitre is common, but below this place it is rare. As such excellent results have been got from treating this condition in its initial stages with sodium iodide the suggestion is made that preventive measures should be taken against goitre in the particular districts affected. The expense of such measures would be trifling and could easily be carried out by the school medical staff. An excellent provisional scheme such as is carried out in certain goitrous districts in Switzerland is suggested. Dr. Eustace Hill reports that an extra medical officer is required to complete the necessary code inspections, and by the appointment of an additional nurse a third school clinic which is urgently needed could be staffed.

Gloucestershire.

Dr. J. Middleton Martin records substantial improvement in the cleanliness of the children, the number of children with dirty heads having been reduced from 25 to 11 per cent. in the last ten years or so. Treatment for defects is also going ahead rapidly. At present the scheme for treatment covers only about one-third of the county, but provisional proposals have been made whereby it can readily be extended to embrace the whole area. Dr. Martin urges that the cost of extending the present arrangements to cover the whole county would be approximately only double the present expense. There is one well-coördinated scheme providing for maternity and child welfare and treatment of school-children. Ten schools in the Cinderford area were closed during the year by order of the district council on account of small-pox, and one of the assistant medical officers, Dr. T. F. Blake, who was released for this purpose from ordinary school work, gave valuable help in connexion with the outbreak by discovering in the schools four missed cases of small-pox.

Leamington Spa.

The number of children examined in the three code groups was 1169. Excluding dental defects and uncleanliness, only 8·7 per cent. of these children were found to have defects requiring medical treatment. There is still, unfortunately, a percentage of 57 of unvaccinated children. Twelve cases of goitre were noted, and in five instances a family history of the disease was recorded.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED SEPT. 13TH, 1924.

Notifications.—The following cases of infectious disease were notified during the week, namely:—Small-pox, 54; scarlet fever, 1600; diphtheria, 733; enteric fever, 120; pneumonia, 443; puerperal fever, 41; cerebro-spinal fever, 9; acute poliomyelitis, 23; *acute polio-encephalitis*, 3; encephalitis lethargica, 43; typhus fever, 1; dysentery, 2; ophthalmia neonatorum, 123. There were no cases of cholera or plague notified during the week. The case of typhus was again from St. Helens.

Deaths.—In the aggregate of great towns, including London, there were 3 deaths from enteric fever, none from small-pox, 16 from scarlet fever, 22 from diphtheria, 9 from measles, 18 from influenza. In London itself the diphtheria deaths numbered 7, and the deaths from infantile diarrhœa, which had been 22, 25, and 30 in the preceding three weeks, declined to 23. Another death from typhus was registered from St. Helens.

Chicken-pox Notifiable.—Ashton-under-Lyne Town Council, in consequence of an outbreak of small-pox, the first for 17 years, has made chicken-pox a notifiable disease for the next six months. Three cases of small-pox have been reported and all contacts have been revaccinated.

Public Health Services.

THE OUTBREAK OF TYPHUS FEVER IN ST. HELENS.

WE are indebted to Dr. Frank Hauxwell, medical officer of health for St. Helens, for some details of the recent outbreak of typhus in that county borough. The first case was discovered on August 12th. After having been ill at home for nearly a week, a girl, aged 14, was sent to the isolation hospital from 18, Bold-street, on the evening of August 11th, by her own doctor as suffering from measles. When seen next day by a medical officer of the health department typhus was suspected, and this was later confirmed by Dr. W. Hanna, of Liverpool. This child died three days after admission. In following this case up it was found on visiting the home that the father had also been ill at home for nearly a week and was being treated for "influenza." He also proved to be suffering from typhus fever and was removed to hospital on August 13th, where he made a good recovery. In pursuing inquiries further it was found that about a month previously (July 13th) another child from the same house had been taken seriously ill and had been treated in the Providence Hospital for "pneumonia," being discharged well from that hospital on August 10th. From a consideration of the history of this case and from the result of a blood-test taken since, there is no doubt that this also was a case of typhus and, so far as is known, the first case of the present outbreak.

The infection had existed, therefore, in the town for at least a month before it came to the knowledge of the health department. The home of this family is in one of the poorer localities of the town and the bedrooms were very dirty, beds and bedding infested with vermin, as also were many cracks and crevices in the plaster. Structurally the house is not in bad sanitary condition. The sleeping accommodation consisted of two upstairs rooms; father, mother, and baby being accommodated in one bedroom, three children in the other. There were no lodgers nor, so far as could be ascertained, had there been any.

On the day following admission of the father to hospital the whole of the remainder of the family, consisting of the mother and three children—i.e., the immediate contacts—were admitted to hospital with a view to personal cleansing and disinfestation and to allow of thorough cleansing of the house. Bedding and wearing apparel were disinfected by steam. Mattresses, flock beds, and a sofa were found to be so infested with vermin that it was considered advisable to destroy them and compensate the owners. The house itself was thoroughly disinfected by spraying, and by arrangement with the owner the walls and ceilings were stripped and re-covered. Other possible contacts were kept under daily observation by a health visitor. The mother and three children were allowed to return home, having been in hospital for eight days. Dr. Hauxwell points out the difficulty there is in enforcing isolation of contacts; this can only be done by application of the local authority to two justices for a removal order, a proceeding which means delay to such an extent as to nullify its value.

The next case to occur was a child, aged 5, sister of the original case. This child was taken ill on August 28th—i.e., 15 days since the removal of the last case and seven days after discharge from hospital as a contact. She was seen on August 29th by the family doctor, who reserved his opinion; later, on the same day a medical officer of the health department diagnosed typhus and the child was removed to the isolation hospital, where she made a good recovery. On the afternoon of August 30th the mother took to bed because she "felt too weak to walk," and when visited on the next day (31st) was also diagnosed typhus and removed to hospital, where she died on Sept. 8th.

In following up the contacts of these cases a sister-in-law, living at 42, Liverpool-street, who had been in more or less close contact with the family, was found on August 31st to be suffering from the disease. She had been under observation since the commencement of the outbreak, and though visited daily said she was perfectly well, yet when detected she had a temperature of 103° F. and was a well-marked case. She was removed to hospital the same day and died there on Sept. 5th. These three cases illustrate the difficulty experienced in dealing with contacts. They had been seen daily by the health visitor, frequently also by a medical officer, and by the sanitary inspector. No indication was obtainable that they were other than well, and yet they must have been—especially in the last case—ill some days previous to discovery, and only willing afterwards to admit that this was so.

The next case to occur was in one of the contacts under observation, a lad, aged 22, living at 44, Liverpool-street. He was found in the early stage of the disease on Sept. 7th and was removed to hospital the same day. In dealing with these later cases the same procedure was adopted as in the earlier cases. The immediate contacts, so far as possible, were removed to hospital with the hope of keeping them there for at least 21 days so as to cover the incubation period. All other contacts are visited daily. Contacts not admitted to hospital are sent there for a bath and disinfection of clothing. Bedding and clothing are disinfected by steam, mattresses and articles which cannot be disinfected are destroyed and compensation paid. The houses are disinfected and the walls stripped and cleansed. Dr. Hauxwell acknowledges the ready compliance of house owners with his wishes.

Further steps being taken with a view to limiting the spread of the disease are as follows: (*a*) House-to-house visitation in the immediate vicinity by one of the sanitary inspectors; where necessary, disinfection of the house and lime-washing of walls is recommended, lime-wash and brush being supplied for the purpose; if necessary official notice to cleanse under Public Health Act, 1875, Section 46, is served; disinfection of bedding, clothing, and of persons offered wherever advisable. (*b*) Special attention regarding cleanliness to scholars attending schools in the immediate vicinity, since mild or abortive cases are apt to occur in children; inquiry regarding all absentees. (*c*) All cases of illness in the vicinity inquired into as far as possible. (*d*) Issue of leaflet and posters drawing attention to the dangers of the disease and importance of cleanliness in fighting it.

So far there have been eight cases, with four deaths. The last case occurred on Sept. 13th in a boy of 12, who had been detained as a contact at the hospital since Sept. 1st. Ten contacts are at present in hospital and 90 others are under supervision.

SMALL-POX IN ENGLAND AND WALES DURING 1924.

UP to the end of the second week in September small-pox appeared in 91 sanitary (including port) districts, the total number of cases being approximately 2750, as compared with 1840 in the corresponding period of 1923. Derbyshire accounts for 1080 cases in 16 sanitary districts (more than one half in the borough and rural district of Chesterfield); Nottingham for 434 cases in 10 districts. 386 cases occurred in Yorkshire (mainly in Middlesbrough) and 306 in Northumberland (mainly in Ashington).

At the present time small-pox is prevalent in Middlesbrough, Chesterfield, and the urban district of Hucknall, in all of which districts the disease has continued to be present since the autumn of 1923. Other sanitary districts now mainly affected are Derby, Mansfield, the rural district of Chesterfield, and the urban districts of Mansfield Woodhouse, Ashington, Melton Mowbray, and Gainsborough. Within the last four weeks sporadic cases have occurred in 21 other sanitary districts, including the metrolaboratories of the Fund, published in THE LANCET of July 26th, 1924, was probably his last public utterance of importance.

Sidney Martin was a sincere worker and a clear thinker. He was impatient of dullness and prolixity in colleagues or students, but had no sarcasm for the tiresome garrulous patient. He was a pioneer in a forest which is now being systematically cleared, a region where chemistry and physiology jointly throw light on disease, and his labours were directed towards the removal of just those obstructions which subsequent workers have found it necessary to attack.

Medical News.

CHELSEA CLINICAL SOCIETY.—The annual dinner of the Society is arranged to take place at the Café Royal, Regent-street, London, on Tuesday, Oct. 21st, at 7 for 7.30 P.M.

LONDON MEDICAL SCHOOL DINNERS.—Owing to the sudden death of Dr. Sidney Martin, senior physician to University College Hospital, the dinner of the past and present students of the hospital, which was to be held at the Hotel Cecil on Oct. 3rd, has been postponed to some date to be arranged in December.—The following is a diary of the other London medical school dinners, fuller details of which appeared in our columns last week: *Wednesday, Oct. 1st*: St. Bartholomew's Hospital, in the Great Hall of the hospital; Charing Cross Hospital, in Gatti's Restaurant, Strand; St. George's Hospital, in the New Hotel Metropole; King's College Hospital, in the Connaught Rooms, Great Queen-street; London Hospital, in the Trocadero Restaurant, Shaftesbury-avenue; Middlesex Hospital, in the Hotel Cecil.—*Monday, Oct. 6th*: St. Mary's Hospital, in the Connaught Rooms, Great Queen-street.—*Friday, Oct. 24th*: St. Thomas's Hospital, in Prince's Restaurant, Piccadilly.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—The opening of the winter session of the School of Pharmacy, 17, Bloomsbury-square, London, W.C., will take place on Oct. 1st at 3 P.M., when the President, Mr. F. Pilkington Sargeant, will present the Pereira Medal and deliver the inaugural sessional address.

MEDICAL OFFICERS OF SCHOOLS ASSOCIATION.—A meeting will be held at 11, Chandos-street, Cavendish-square, London, W. 1, on Oct. 8th, at 5 P.M., when a discussion on the relative values of stone-milled and other flours and breads, in relation to the nutrition of the growing child, will be opened by Dr. Robert Hutchison. There will be illustrative exhibits of stone-milled flours, breads, and other wheaten foods.

PROFESSIONAL AND BUSINESS WOMEN'S HOSPITAL LEAGUE.—Miss Philippa Strachey has succeeded Miss Mildred Ransom as secretary to this League, and after Oct. 1st all communications intended for the League should be addressed to her at 35, Marsham-street, Westminster, London, S.W. 1.

THE LATE DR. DANIEL BIDDLE.—Daniel Biddle, M.R.C.S. Eng., L.S.A., who died at his residence at Kingston-on-Thames on Sept. 14th, was a man of many diverse talents. A son of the late Lieut.-Colonel Biddle, of the Madras Artillery, he was born in Gloucestershire in 1840. He received his early education at Taunton and studied medicine at Somerset County Hospital, at the London University, and at St. Thomas's Hospital, qualifying at the age of 22. After a period as house surgeon at St. Thomas's Hospital, he took up medical and surgical work at Kingston in 1868, where he remained in practice for over 46 years. Since his retirement nearly ten years ago he had been very little in the public eye, but for many years he was a prominent local figure and a member of the Kingston and District Medical Society. He was a distinguished mathematician, and for some years held the post of mathematical editor of the *Educational Times*. He was also an able and accomplished statist and a member of the Royal Statistical Society. He gave valuable asistance to the General Medical Council in the preparation of four special reports issued between the years 1885 and 1887, and it was under his supervision that the census of the medical profession in 1881 and that of 1886 were issued, reports which had their influence on the decision to extend the period of medical studentship to five years. A pioneer in the standardisation of medical fees, Dr. Biddle founded for this purpose the Thames Valley Medical Association. He took a leading part in the agitation against the dual system of notification embodied in the Infectious Diseases Act of 1889, and carried the opposition into both Houses of Parliament. He contributed a paper on the subject to the Section of State Hygiene at the International Congress of Hygiene and Demography held in London in 1891, in addition to articles to the lay and medical press. His many interests included such subjects as aeronautics, theology, genealogy, and shorthand, to all of which he made original contributions, having invented a special type of balloon as well as a new system of shorthand. For 20 years he advocated on scientific grounds the legalising of marriage with a deceased wife's sister. Dr. Biddle is survived by five daughters, his wife having predeceased him in 1904.

INTERNATIONAL DENTAL EXHIBITION.—This exhibition, under the auspices of the Incorporated Dental Society, will again be held this year at the University of London Imperial Institute, South Kensington, S.W. 7, opening on Sept. 29th for one week.

DONATIONS AND BEQUESTS.—By the will of the late Mr. W. H. Revis, of Nottingham, the testator left, among other bequests, £3000 to the Nottingham General Hospital and £500 to the Fielding Palmer Cottage Hospital at Lutterworth.—The Royal Northern Hospital, Holloway, has received £1000, a share of the residue of the estate of the late Mr. Arthur Daniel Serena.—Mr. Frederick Fountain has bequeathed to the Miller General Hospital for South-East London a house known as Cedar Bank as a convalescent home and £12,000 as an endowment for its upkeep.—The executors of the late Lieut.-Colonel T. Thornycroft Vernon have given £1200 for the endowment of a bed in the male ward of the Chester Royal Infirmary.—Sir Ewen J. Maclean, professor of obstetrics and gynæcology in the Welsh National School of Medicine, has given 1000 guineas to the Royal Infirmary, Cardiff, to endow an "Agnes Maclean" bed in memory of his mother.

NATIONAL MEDICAL UNION.—This Union is making an effort to collect evidence of medical opinion throughout the country, in support of its policy, for presentation to the forthcoming Royal Commission on National Health Insurance. The essence of this policy is: (1) That a State Medical Service is necessary only for genuinely necessitous persons, otherwise defined as destitute persons or as persons temporarily or permanently unable to provide for themselves. (2) That the matter of insurance against the financial risks of sickness, of which, in principle, the Union approves, should have separate treatment. The Union proposes that this should be effected by a genuine system of insurance against doctors' bills, cost of drugs, institutional treatment, &c., and that the profession of medicine should be left absolutely free from State interference to develop on the traditional lines of private practice. The National Deposit Friendly Society and the Scottish Clerks' Association are cited as examples of the type of insurance indicated before the present Act came into force. A circular letter has been issued signed by Drs. A. Blackhall-Morison, W. Russell, and J. Howson Ray, with the request that approval of the policy should be communicated to Dr. E. H. Worth, hon. sec., National Medical Union, 11, Chandos-street, London, W. 1.

HERBAL REMEDIES: A REMARKABLE COINCIDENCE.

MEDICAL practitioners are receiving through the post a pamphlet issued by Heath and Heather, herb specialists, of St. Albans, which contains a list of herbal remedies and notes on their adaptability to the treatment of common illnesses. "There has been a most remarkable improvement," the pamphlet states, "in the health of the nation during the last three years," and goes on to add: "It is a remarkable coincidence that for those three years Heath and Heather were in business." The coincidence is not so difficult to explain as the statement on page 86 of the pamphlet asking readers to "consider that of the children born in the homes of merry England, only two-thirds reach the age of one year, and that quite half of those who survive carry with them all their lives some physical imperfection inherited from previous generations." From this it is a small step to the deduction that, as medical knowledge presumably advances, physical deterioration also creeps on. A printed slip enclosed in the pamphlet states that owing largely to the child welfare movement the death-rate among children under one year of age was only 60 per 1000 last year, but adds that the remark on page 86 was accurate when the passage was written "some years ago." If it was accurate when written it cannot have been written since the Wars of the Roses. It is hardly a coincidence that such colossal ignorance of vital statistics should coincide with outrageous claims for the properties of herbs. Packet 25, for instance, will form a complete cure for diabetes in its early stages.

Obituary.

SIDNEY HARRIS COX MARTIN, M.D., F.R.C.P., B.Sc. Lond., M.R.C.S. Eng., F.R.S.

The sudden death on Sept. 22nd of Dr. Sidney Martin will distress all who have come into contact with him as colleague, physician, or teacher. His interests had a wide range—from biology, which gained him the degree of B.Sc. Lond. in 1878, through physiology and pathology to clinical medicine. It is small wonder that even the iconoclasts among the younger medical scientists of to-day speak respectfully of his clinical acumen, tempered and controlled by such wide general knowledge. Indeed, the willing services of Dr. Martin were often commandeered by sick colleagues, to whom his gruff optimism brought more cheer than did the suave urbanities of a polished bedside manner.

Sidney Martin was born in Jamaica in 1860, and was educated at University College, London, and in Vienna. After taking his science degree he turned to the study of medicine, qualifying M.R.C.S. Eng. in 1882, M.B., B.S. Lond. in 1883, taking the University scholarship in medicine and honours in surgery, and M.D. Lond in 1884, and becoming successively Member and Fellow of the Royal College of Physicians on London a few years later. The scientific aspect of medicine claimed him from the first, and he became pathologist, curator to the museum, and medical tutor to the Middlesex Hospital and pathologist and medical registrar to the City of London Hospital for Diseases of the Chest. The physiology and pathology of digestion intrigued Martin throughout his career, and his studies on protein metabolism in health and disease, the subject of a communication to the Section of Pathology of the B.M.A. in 1890, led him to investigate the chemical pathology of protein poisons in infective disorders. In his Goulstonian lectures, published in The Lancet,[1] he compared the chemical pathology of diphtheria with that of anthrax, infective endocarditis, and tetanus. The main thesis of these lectures would not be disputed to-day—that knowledge of the morphology of the primary infective agent cannot explain the symptoms of disease, and that, beside the study of the causative organism and of the histological lesion, investigation of the poisonous product of the infective agent is needed. The further prosecution of his studies into the chemical products of pathogenic bacteria formed the subject of his Croonian lectures[2] in 1898, by which time Martin was both a Fellow and professor of pathology at University College, and also assistant physician to University College Hospital and to the Hospital for Consumption at Brompton. Experimental pathology was still despised by many physicians as irrelevant to medical work, but Martin was even at this time a firm defender of controlled animal experiments to supplement clinical observation of patients, which, however, he neither underrated nor neglected. In 1895 he wrote a book on Functional and Organic Disease of the Stomach, and he continued for many years to publish contributions to books (notably to Gibson's Text-book of Medicine, Quain's Dictionary of Medicine, Bain's Text-book of Practical Medicine, and Clifford Allbutt's System of Medicine), and to journals on the disorders of the digestive system. His Lettsomian lectures, delivered in 1909, were on Functional Disorders of the Stomach and Intestines, and the Lumleian lectures in 1915 on Chronic Infections of the Colon completed this long series of observations on the pathology of the digestive tract.

Meanwhile, however, Martin's critical faculties were being used in another field, in connexion with the Royal Commission appointed in 1890, and reappointed in 1894, to inquire into the effect of food derived from tuberculous animals on human health. The object of the investigation was to determine whether the meat and milk of tuberculous cows was capable of transmitting the disease, and his Appendix to the Report, issued in 1896, described with great minuteness and exactness a very detailed inquiry. A large part of the Report of the Royal Commission consisted in the evaluation of Martin's conclusions, which were adopted generally by the Commission, who regarded it as established that any person who takes tuberculous matter into the body as food incurs risk of acquiring tuberculous disease. In 1895 Martin was made a Fellow of the Royal Society, and in 1903 he published his well-known text-book on pathology. In this book he recognised that his title would cover two great groups of work, morbid histology and general pathology, but he deals only with the latter, assuming in the reader some practical familiarity with the former and with the elements of bacteriology. The work was recognised at once by all as of high excellence, giving a complete survey, at the time of its issue, of a rapidly growing subject, and familiarising the learner with the problems presented by infection and immunity as well as with the phenomena and results of inflammation. The many concise and lucid summaries formed a feature of this valuable text-book.

During the war Sidney Martin was attached to the Third London General Hospital at Wandsworth and worked strenuously, since his duties as physician and professor of clinical medicine of University College Hospital could not be neglected, and were carried on concurrently with his war work. This was not confined to a duplication of his clinical responsibilities. In March, 1916, a committee was appointed by the Royal Colleges of Physicians and Surgeons to advise the Government in relation to medical practitioners in the metropolitan district required for service in the army, including members of the staffs of the London medical schools and hospitals. Sidney Martin was one of the first representatives of the Royal College of Physicians on this committee, afterwards known as the Committee of Reference, and was made chairman of the subcommittee which dealt with appeals submitted on behalf of hospitals against the undue depletion of their staffs, as well as with the preparation of lists of those who could properly be called on for war service. This subcommittee met frequently and its labours were onerous. Martin was always at his place in the chair, and his judgment, tact, and power of rapidly seeing the essential factors in each case through the maze of detail presented rendered his services of the greatest value. He represented the Committee of Reference in the joint deliberations with the Central Medical War Committee, and took a prominent part in drafting a report of the Joint Committees on the treatment of discharged disabled soldiers, having already been largely responsible for an important report on the medical treatment of dischargeable disabled soldiers in 1916. He was one of the assessors under the Appeals Tribunal of the Local Government Board, and became chairman of the subcommittee of the Committee of Reference dealing with the proceedings of the Boards of Assessors.

Sidney Martin was privileged to serve the Royal College of Physicians throughout his career. He was a member of the Joint Committee of the Royal Colleges of Physicians and Surgeons which controlled the laboratories on the Embankment in which original research was carried on from 1900 to 1905. He was examiner in medicine on the Conjoint Board of the Royal Colleges from 1907 to 1910, a member of the Council of the Royal College of Physicians in 1910–11, a censor in 1915–16, and was selected to represent the College on the Senate of the University of London in 1919. Moreover, on the foundation of the Imperial Cancer Research Fund in 1902, Dr. Martin was appointed on its executive committee as one of the representatives of the Royal College of Physicians, and he remained a member until his death. On the retirement of Sir William Church from the chairmanship of this committee last year, Sidney Martin was appointed to succeed him, and his clear summary of the recent work carried out in the

THE PHYSIOLOGY OF A COMMON COLD.

By S. E. Kark, M.B., Ch.B. Edin.,

NEW SOMERSET HOSPITAL, CAPE TOWN.

SINCE the acceptance in medicine of the microbic origin of disease, a tendency has been noticeable to look to external and accidental factors, rather than to internal physiological causes, for the incidence of many maladies. That everyday disease, the "common cold," comes under the same category. Its origin has been traced on laboratory evidence to microbic infection, but that microbic invasion is not the primary cause is evident for several reasons :—

(1) A common cold does not per se produce the usual concomitants of infection—rise of temperature, quickened pulse, and the like.

(2) It is generally brought about by sudden changes of temperature—e.g., on emerging from a warm room into the cold air, discarding warm clothing habitually worn, sudden atmospheric changes frequent in spring and autumn.

(3) The onset can be produced experimentally by exposing any part of the body ordinarily protected against cold to the effects of a chilling draught.

Current Explanation Inadequate.

The usual explanation, that the lowered vitality due to the chill makes the body more susceptible to infection, is hardly adequate. For the nasal chambers were not exposed to new organisms while the cold was being induced. The organisms present in the nose—saprophytic until the chill began to work—surely must require time to assume virulence. All infections have a longer or shorter incubation period, while a "cold" becomes manifest almost immediately after exposure. Other vitality-lowering agencies, such as hæmorrhages, never induce colds. I am therefore led to believe that a common cold is the result of a physiological process overdone : a normal function turned into the pathological—as a good many pathological conditions are—through Nature being stimulated to over-activity on being called upon to act precipitately in defence.

Now, the physical quality of evaporation as a temperature-lowering agent is well known. Nature, indeed, has made use of its cooling effects by incorporating it as an adjunct to the heat-regulating centre of the body, as is seen when we perspire on a hot day. In the nasal passages we have two roomy chambers, with a surface area augmented by the convolutions of the turbinates : from this large surface, normally constantly moist, it is estimated that one litre of water is evaporated every 24 hours. It is reasonable to assume that it is one of the functions of the nasal chambers thus to act as an auxiliary to the heat-regulating centre. Through these moist chambers a current of air is constantly passing. The evaporation resulting therefrom must be considerable, and as a consequence the temperature-lowering effects on the nasal mucous membrane produced by this constant evaporation must likewise be quite considerable. The cooled blood from the nasal chambers entering the general circulation must in its turn help to lower the general body temperature.

Emergency Heat Regulation.

Under normal conditions the loss of heat to the body resulting from the nasal evaporation is adjusted through the heat-regulating centre, as all other bodily heat losses are, by heat production through metabolic changes. But when too sudden a demand is made on the heat-regulating mechanism, it cannot be balanced immediately by heat production. Nature, then, has recourse to another expedient, and that is, by stopping as soon as possible all the heat leakages which are generally going on in the body. As an example of this may be cited the contraction of the skin vessels on exposure to cold. Loss of heat through the nasal chambers may be eliminated in two ways :

(a) *By acting on the cooling medium ;* turning off, so to speak, the tap of the chamber containing the cooled blood by retarding the rate of its inflow into the general circulation.

(b) *By acting on the cooling agent ;* diminishing the air current passing through the nasal chambers.

These two actions are accomplished by the heat-regulating centre in two ways. The nasal mucous membrane has a large vaso-motor nerve-supply as well as very numerous nets of blood-vessels. By sudden vaso-motor paresis a marked stasis and congestion of the nasal mucous membrane takes place. The rate of flow of cooled blood into the general circulation is thus greatly retarded. The stasis and congestion produce at the same time a definite swelling of the erectile mucous membrane of the inferior and middle turbinates and of the anterior part of the septum. The air-way is diminished, with the result that the volume of air that can pass, the evaporation and its resulting cooling effects, are all proportionally reduced. Moisture accumulates in the chamber—the cause of the running nose—and this again helps further to diminish the volume of air passing.

In addition to this vaso-motor controlling action, respiration also plays a part in the adjustment of both the cooling agent and the cooling medium. For, on exposing the body to the effects of cold the breath is held, respiration is first temporarily inhibited, and if the exposure to the cold is continued, respiration becomes shallow. This, too, has a double effect. The volume of air passing through the nasal passages is further lessened, while the suction action of inspiration on the nasal circulation is diminished. Hence, the congestion of the nasal mucous membrane is still more favoured. The importance of this suction action is demonstrated by the ease with which a partial blockage of the nose is often overcome by a few deep inspirations.

Response of Defensive Nature.

In this view a common cold is primarily a physiological process, a local response of a defensive nature to a sudden physiological demand. It is only afterwards, when congestion and stasis have been established, when warm moist air—now almost stationary—fills the nasal cavities, that microbic growth contributes its quota to the aggravation of the trouble.

Since this sudden application by the heat-regulating centre of the vaso-motor and respiratory brakes, in order to stop the heat leakages through the nasal chambers, must interfere with the normal functions of the nose, it stands to reason that Nature would make use of this method only as an emergency measure : under certain contingencies which would arise for instance :—

(a) When the heat-regulating centre itself is faulty. This is the case in very young children whose mechanism, compared with that of an adult, functions imperfectly. For, while an adult's temperature generally remains constant irrespective of the temperature by which he is surrounded, that of a child fluctuates to some degree in accordance with the variations in temperature of the bodies with which it comes in contact. This imperfect working of the heat-regulating mechanism in the child accounts for the susceptibility of children to catarrh of the upper air-passages.

(b) When the auxiliaries to the heat-regulating centre do not act well—e.g., when the skin through too much protection of warm clothing has not been allowed to react quickly to sudden changes in temperature. Thus people who are apt to coddle catch cold easily, while soldiers and those who lead an open life do not.

(c) When the heat-regulating centre has to act precipitately, as on sudden exposure to a draught, or during sudden temperature changes as in spring and autumn.

Prophylaxis.

The better the heat-regulating centre is functioning, and the more responsive are its auxiliaries—the skin and vaso-motor nerves—the less occasion would arise under sudden strain for panicky action and its product, the "common cold." It would therefore seem that the prevention of the onset of common colds can best be achieved by training and developing the auxiliaries of the heat-regulating centre to respond quickly to altered temperature conditions. Children ought to be hardened from infancy, cold sponging should follow the daily tepid bath, older children should have a cold shower. Children should not be overburdened with too much clothing. Finally, breathing exercises relieve and overcome nasal congestion, the suction action of deep inspiration improving the circulation and the tone of the nasal mucous membrane.

MENTAL HOSPITALS IN THE EAST.

THE recently published "Triennial Reports for the Mental Hospitals of Assam, Burma, and the Punjab," covering the period 1921–23, reveal closely similar conditions in lunacy administration in these three States. The most important change is a slow but steady increase in the numbers of certified insane. Whether this be due to the more efficient detection of mental disease, or actually to a general increase in the prevalence of insanity, is not suggested. Since the population of mental hospitals is apparently increasing all over the world, it is of the greatest interest to ascertain whether this indicates an increased ratio of sane to insane among the general population, and if so, upon what factors this change depends. In reports from such distant parts of the world as these, whose conditions it is impossible to

THE PHYSIOLOGY OF A COMMON COLD.

BY S. E. KARK, M.B., CH.B. EDIN.,

NEW SOMERSET HOSPITAL, CAPE TOWN.

SINCE the acceptance in medicine of the microbic origin of disease, a tendency has been noticeable to look to external and accidental factors, rather than to internal physiological causes, for the incidence of many maladies. That everyday disease, the "common cold," comes under the same category. Its origin has been traced on laboratory evidence to microbic infection, but that microbic invasion is not the primary cause is evident for several reasons :—

(1) A common cold does not per se produce the usual concomitants of infection—rise of temperature, quickened pulse, and the like.

(2) It is generally brought about by sudden changes of temperature—e.g., on emerging from a warm room into the cold air, discarding warm clothing habitually worn, sudden atmospheric changes frequent in spring and autumn.

(3) The onset can be produced experimentally by exposing any part of the body ordinarily protected against cold to the effects of a chilling draught.

Current Explanation Inadequate.

The usual explanation, that the lowered vitality due to the chill makes the body more susceptible to infection, is hardly adequate. For the nasal chambers were not exposed to new organisms while the cold was being induced. The organisms present in the nose—saprophytic until the chill began to work—surely must require time to assume virulence. All infections have a longer or shorter incubation period, while a "cold" becomes manifest almost immediately after exposure. Other vitality-lowering agencies, such as hæmorrhages, never induce colds. I am therefore led to believe that a common cold is the result of a physiological process overdone : a normal function turned into the pathological—as a good many pathological conditions are—through Nature being stimulated to over-activity on being called upon to act precipitately in defence.

Now, the physical quality of evaporation as a temperature-lowering agent is well known. Nature, indeed, has made use of its cooling effects by incorporating it as an adjunct to the heat-regulating centre of the body, as is seen when we perspire on a hot day. In the nasal passages we have two roomy chambers, with a surface area augmented by the convolutions of the turbinates : from this large surface, normally constantly moist, it is estimated that one litre of water is evaporated every 24 hours. It is reasonable to assume that it is one of the functions of the nasal chambers thus to act as an auxiliary to the heat-regulating centre. Through these moist chambers a current of air is constantly passing. The evaporation resulting therefrom must be considerable, and as a consequence the temperature-lowering effects on the nasal mucous membrane produced by this constant evaporation must likewise be quite considerable. The cooled blood from the nasal chambers entering the general circulation must in its turn help to lower the general body temperature.

Emergency Heat Regulation.

Under normal conditions the loss of heat to the body resulting from the nasal evaporation is adjusted through the heat-regulating centre, as all other bodily heat losses are, by heat production through metabolic changes. But when too sudden a demand is made on the heat-regulating mechanism, it cannot be balanced immediately by heat production. Nature, then, has recourse to another expedient, and that is, by stopping as soon as possible all the heat leakages which are generally going on in the body. As an example of this may be cited the contraction of the skin vessels on exposure to cold. Loss of heat through the nasal chambers may be eliminated in two ways :

(*a*) *By acting on the cooling medium* ; turning off, so to speak, the tap of the chamber containing the cooled blood by retarding the rate of its inflow into the general circulation.

(*b*) *By acting on the cooling agent* ; diminishing the air current passing through the nasal chambers.

These two actions are accomplished by the heat-regulating centre in two ways. The nasal mucous membrane has a large vaso-motor nerve-supply as well as very numerous nets of blood-vessels. By sudden vaso-motor paresis a marked stasis and congestion of the nasal mucous membrane takes place. The rate of flow of cooled blood into the general circulation is thus greatly retarded. The stasis and congestion produce at the same time a definite swelling of the erectile mucous membrane of the inferior and middle turbinates and of the anterior part of the septum. The air-way is diminished, with the result that the volume of air that can pass, the evaporation and its resulting cooling effects, are all proportionally reduced. Moisture accumulates in the chamber—the cause of the running nose—and this again helps further to diminish the volume of air passing.

In addition to this vaso-motor controlling action, respiration also plays a part in the adjustment of both the cooling agent and the cooling medium. For, on exposing the body to the effects of cold the breath is held, respiration is first temporarily inhibited, and if the exposure to the cold is continued, respiration becomes shallow. This, too, has a double effect. The volume of air passing through the nasal passages is further lessened, while the suction action of inspiration on the nasal circulation is diminished. Hence, the congestion of the nasal mucous membrane is still more favoured. The importance of this suction action is demonstrated by the ease with which a partial blockage of the nose is often overcome by a few deep inspirations.

Response of Defensive Nature.

In this view a common cold is primarily a physiological process, a local response of a defensive nature to a sudden physiological demand. It is only afterwards, when congestion and stasis have been established, when warm moist air—now almost stationary—fills the nasal cavities, that microbic growth contributes its quota to the aggravation of the trouble.

Since this sudden application by the heat-regulating centre of the vaso-motor and respiratory brakes, in order to stop the heat leakages through the nasal chambers, must interfere with the normal functions of the nose, it stands to reason that Nature would make use of this method only as an emergency measure : under certain contingencies which would arise for instance :—

(*a*) When the heat-regulating centre itself is faulty. This is the case in very young children whose mechanism, compared with that of an adult, functions imperfectly. For, while an adult's temperature generally remains constant irrespective of the temperature by which he is surrounded, that of a child fluctuates to some degree in accordance with the variations in temperature of the bodies with which it comes in contact. This imperfect working of the heat-regulating mechanism in the child accounts for the susceptibility of children to catarrh of the upper air-passages.

(*b*) When the auxiliaries to the heat-regulating centre do not act well—e.g., when the skin through too much protection of warm clothing has not been allowed to react quickly to sudden changes in temperature. Thus people who are apt to coddle catch cold easily, while soldiers and those who lead an open life do not.

(*c*) When the heat-regulating centre has to act precipitately, as on sudden exposure to a draught, or during sudden temperature changes as in spring and autumn.

Prophylaxis.

The better the heat-regulating centre is functioning, and the more responsive are its auxiliaries—the skin and vaso-motor nerves—the less occasion would arise under sudden strain for panicky action and its product, the "common cold." It would therefore seem that the prevention of the onset of common colds can best be achieved by training and developing the auxiliaries of the heat-regulating centre to respond quickly to altered temperature conditions. Children ought to be hardened from infancy, cold sponging should follow the daily tepid bath, older children should have a cold shower. Children should not be overburdened with too much clothing. Finally, breathing exercises relieve and overcome nasal congestion, the suction action of deep inspiration improving the circulation and the tone of the nasal mucous membrane.

MENTAL HOSPITALS IN THE EAST.

THE recently published "Triennial Reports for the Mental Hospitals of Assam, Burma, and the Punjab," covering the period 1921–23, reveal closely similar conditions in lunacy administration in these three States. The most important change is a slow but steady increase in the numbers of certified insane. Whether this be due to the more efficient detection of mental disease, or actually to a general increase in the prevalence of insanity, is not suggested. Since the population of mental hospitals is apparently increasing all over the world, it is of the greatest interest to ascertain whether this indicates an increased ratio of sane to insane among the general population, and if so, upon what factors this change depends. In reports from such distant parts of the world as these, whose conditions it is impossible to visualise for anyone who has not been there, any information, even amounting only to a mere opinion, on this question of universal concern would be of peculiar value.

In consequence of these growing admissions, the mental hospitals of Bengal and Assam have been overcrowded. In the latter place new buildings are projected, a serious feature of the accommodation shortage being that criminal lunatics are being detained for long periods in jail; in Burma a new hospital is actually in progress of erection. In the Punjab a new criminal asylum has been built, and the tuberculous section of the Lahore asylum has been extended. The complete segregation of tuberculous subjects in this asylum is an example which might well be followed in many English institutions; recently the treatment of these patients has included sodium morrhuate injections carried out on a large scale. Lahore is also peculiar in that the female section is entirely staffed by Franciscan nuns. This introduces another point on which a stranger to India might well desire some explanation, and that is the fact that in all these hospitals there are about five times as many males as females. There is general complaint of inadequate information as to past histories, and diagnosis in the absence of any information as to the patient's antecedents is often difficult. The majority are admitted in a poor state of physical health, due most commonly to dysentery or some other form of infective diarrhœa, to tuberculosis, or *Cannabis indica*. Malaria appears to have its highest incidence in Assam, and ascaris infection is prominent in Burma. There has been a general improvement in administration. Attendants are better paid, and consequently of a more trustworthy type. Patients are better fed, and are allowed much more liberty: a large proportion are employed, both on work for the benefit of the institution, and on large-scale manufacture which brings considerable profits. In one of these reports it is mentioned that patients are paid for their work, this money enabling them to buy such things as sweets and tobacco from the asylum bazaar.

Difficult as it is to picture the conditions under which these patients live and are treated, such impressions as can be gained from these reports are particularly encouraging, and certainly reflect favourably on the Indian administration.

PUBLIC HEALTH IN TOGOLAND.

IN the report for the year 1923 on the British sphere of the mandated territory of Togoland it is explained that this was a German colony until August, 1914, when it was surrendered to the combined British and French forces. The territory lies between the Gold Coast and the French colony of Dahomey; its area is approximately 33,000 square miles, with a population estimated to be 1,000,000. A provisional agreement was made partitioning the colony into the British sphere and the French sphere; and the portion of Togoland now mandated to Great Britain is being administered as an integral part of the Gold Coast and its dependencies. In the portion of the report devoted to medical matters, it is stated that the most important disease in the southern area is venereal. It is not an exaggerated statement that one in every five of the population is infected. Out of 1498 patients attending the hospital at Ho during the year this disease accounted for no less than 300. One of the German methods in combating the disease was the recognition of licensed houses in the main centres, where the inhabitants of brothels were compelled to report themselves to the medical officers for examination once a week. This system, however, is repugnant to British ideas and would not be tolerated. The Government fully realise the importance of the matter, and medical officers always advise the natives to report themselves without delay for treatment when suffering in the first stage of the disease. In the northern area venereal disease is practically negligible. The medical officer at Ho writes: "Malaria and helminthiasis are next in importance and are very common, as should be expected. Sleeping sickness has not yet been met with, but leprosy is prevalent, and, I believe, is more common than is generally known. The health of the people, on the whole, is not too bad. If they would only come for treatment at once, instead of giving the medicine man a trial, one would be able to get more satisfactory reports. It is a regrettable fact that we get a very low percentage of our patients in the first stage of their disease. Even then they take their native concoctions as well as European treatment. Satisfactory progress is made in eradicating the disease of yaws, but even in this case, when all the physical signs have disappeared, they consider themselves recovered and the patients are seen no more. In yaws the effect of even a single injection of salvarsan is very spectacular, and the patient is fully recovered according to his own ideas, and in most cases he is. This, however, makes the native believe that salvarsan is a remedy for all ills; and in cases, for example, of syphilis he will not persist in the treatment for the full course. However, we persevere in the work, in the hope that with time the native will get sufficiently developed mentally to appreciate the fact that he cannot recover from all ills by the same tre ment and in the same space of time." The report that there is a segregation colony for lepers, where patients are housed and treated. This segregation enforced in the town of Yendi, but residence of lepers fr outlying districts is voluntary. The number resident is 2 The treatment of yaws with N.A.B. has practically fr the town of Yendi of the disease, but in spite of acti measures still employed it is very prevalent in the out lying district. Malaria is epidemic and universal, an people of all ages are affected with guinea-worms. Ya and guinea-worms are not only disabling while the disease are active, but cause great deformity afterwards. Thoug the stegomyia and tsetse-fly are common in the district, n cases of yellow fever or sleeping sickness have been dia nosed. Pneumonia and bacillary dysentery are the chi causes of death. The birth-rate is reported to be appro mately 80 to 100 per 1000. Infant mortality is very hi The wife of the officer in charge of the junior trade sch at Yendi is an acting medical officer; she advises the chie of the various towns and villages regarding sanitary improv ments and helps to combat endemic diseases. A num of women emigrate to the coast towns and other big cent for the purpose of prostitution, a profession which appe in their opinion, to involve no degradation, with the resu that they return to this territory infected and spread th venereal disease. The principal causes of prostitution are (*a*) the desire of the women to amass affluence in order to purchase finery; (*b*) in many cases discontent with tl status of wedlock among the labouring classes; (*c*) th lack of specific grounds for divorce, the mere inclination o one of the parties to discontinue the union being sufficient t warrant it being dissolved; and (*d*) the system of nativ legal marriage by which a girl is betrothed at birth, an consequently, in many cases, on arriving at the age of puberty refuses to accept the espoused husband arranged for he and cohabits with a paramour.

SOFT WATER IN THE LONDON AREA.

A CORRESPONDENT asks for advice in finding a residentia locality nearer London than the Wey Valley with an equally soft water-supply. This will not be easy, for Wey Valley water has a total hardness of only 2·8–3°. Woburn Sands with 2·8° has an equally soft water, while at Aylesbury and in parts of Dorking the hardness varies from 4·2–5°. The East Surrey Water Company, which softens its supply to about 4·5°, serves Caterham, Warlingham, and Sanderstead, as well as parts of Reigate, Coulsdon, Epsom, and Woldingham. Further information can be obtained from the very complete Return as to Water Undertakings in England and Wales, issued by the Local Government Board in 1915 (H.M. Stationery Office, 5*s.* 1*d.*). Small water softening plants, specially designed for private houses which will soften most supplies down to 3° or less, are obtainable from the United Water Softeners, Imperial House Kingsway (Permutit process). The original hardness o the water and consequently the locality would then be immaterial to the user.

MIRROR WRITING IN AN ADULT.

To the Editor of THE LANCET.

SIR,—Sixteen years ago you published for me a lette describing the mirror writing of a small boy. I have nov met with a still more remarkable case of the same conditio in a young lady doctor who is left-handed, and whos heredity is markedly so. She has from childhood writte thus, and still writes as fluently backwards or forward at will. This is the first case that I have met in which th mirror writing power has been retained to adult life, bu from inquiry I have found that it is not very uncommo in childhood.

I am, Sir, yours faithfully,

VAUGHAN PENDRED, M.D., F.R.C.S. Eng.

East Sheen, Sept. 20th, 1924.

Messrs. H. K. Lewis and Co.'s monthly list of new book and new editions, added to their medical and scientifi circulating library during August, contains the names o 24 books in the medical list and 14 in the scientific an technical list, in each case covering a wide range of subject
